## 1 Math Review

### 1.1 Vector Spaces and Norms

**Definition 1.1** (Vector Space). A vector space  $X$  is a set of elements with two operations, addition (+) and scalar multiplication ( $\cdot$ ), and an additive identity  $\mathbf{0} \in X$  satisfying:

1.  $x + y = y + x$
2.  $(x + y) + z = x + (y + z)$
3.  $\mathbf{0} + x = x, \forall x \in X$
4.  $\alpha(x + y) = \alpha x + \alpha y$
5.  $(\alpha + \beta)x = \alpha x + \beta x$
6.  $(\alpha\beta)x = \alpha(\beta x)$
7.  $0x = \mathbf{0}$  and  $1x = x$

Examples include  $\mathbb{R}^K$  and  $\mathcal{C}[a, b]$ , the set of all continuous functions from  $[a, b] \rightarrow \mathbb{R}$ .

**Definition 1.2** (Norm). Let  $X$  be a vector space. A norm is a functional,  $\|\cdot\| : X \rightarrow \mathbb{R}$  satisfying

1.  $\|x\| \geq 0, \forall x \in X$  and  $\|x\| = 0$  if and only if  $x = \mathbf{0}$ .

---

The most recent version of these notes can be found [here](#).

2.  $\|x + y\| \leq \|x\| + \|y\|$  (Triangle Inequality)
3.  $\|\alpha x\| = |\alpha|\|x\|, \forall \alpha \in \mathbb{R}, x \in X$

Examples of norms include the  $\ell^p$  norms on  $\mathbb{R}^K$  or the sup-norm on the space of all bounded, real valued, functions. On  $\mathbb{R}^K$  all norms are equivalent, which is to say that for any two norms  $\|\cdot\|_1, \|\cdot\|_2$  there are constants  $C_1, C_2$  such that  $C_1\|\cdot\|_2 \leq \|\cdot\|_1 \leq C_2\|\cdot\|_2$ . However, this is not generally the case for functional vector spaces. For example on  $\mathcal{C}[a, b]$  there is no constant  $c$  such that, for all  $f$ :

$$\sup_{x \in [a, b]} f(x) = \|f\|_\infty \leq c\|f\|_2 = \left( \int_a^b f^2(x) dx \right)^{1/2}.$$

Closely related to a norm is the concept of a metric, which is a way of defining a distance on a space.

**Definition 1.3** (Metric). Let  $X$  be a vector space. A metric (or distance metric) on  $X$  is a functional  $d(x, y) : X \times X \rightarrow \mathbb{R}$  satisfying:

1.  $d(x, y) \geq 0, \forall x, y$  and  $d(x, y) = 0 \iff x = y$
2.  $d(x, y) = d(y, x)$
3.  $d(x, y) \leq d(x, z) + d(z, y), \forall x, y, z$

It is straightforward to verify that, given a norm on a vector space  $X$ , we can generate a valid metric:

$$d_{\|\cdot\|}(x, y) := \|x - y\|.$$

We return to these concepts when discussing a topology.

## 1.2 Topology and Continuity

A topology is a general structure under which we can discuss concepts such as convergence and continuity. We can start with a general structure and then discuss spaces where the topology is generated by a metric (or norm).

**Definition 1.4** (Topology). A topology on a set  $X$  is a collection of subsets of  $X$ ,  $\tau \subset 2^X$  satisfying:

1.  $\emptyset, X \in \tau$ .
2.  $\tau$  is closed under finite intersections, if  $\{A_k\}_{k=1}^K \in \tau$  then  $\bigcap_{k=1}^K A_k \in \tau$ .
3.  $\tau$  is closed under arbitrary unions. For any index set  $I$ , if  $\{A_k\}_{k \in I} \in \tau$  then  $\bigcup_{k \in I} A_k \in \tau$ .

The elements of  $A \in \tau$  are called open sets. A set,  $B$ , is closed if its complement is in  $\tau$ ,  $B^c \in \tau$ .

Some simple examples include the trivial topology,  $\tau = \{X, \emptyset\}$  and the discrete topology  $\tau = 2^X$ . Given a topology, we can define some familiar terms:

**Definition 1.5** (Interior). For a subset  $A \subseteq X$ , the interior of  $A$ , denoted  $A^\circ$ , is the largest open set included in  $A$  (where largest is defined under the usual subset ordering). We can also express this as the union of all open sets contained by  $A$ .

$$A^\circ = \bigcup \{B : B \in \tau, B \subseteq A\}.$$

Note that a set is open if and only if  $A = A^\circ$ .

**Definition 1.6** (Closure). For a subset  $A \subseteq X$ , the closure of  $A$ , denoted  $\bar{A}$ , is the smallest closed set the covers  $A$ . We can express this as the intersection of all closed sets containing  $A$ :

$$\bar{A} = \bigcap \{B : B^c \in \tau, A \subseteq B\}.$$

By De-Morgan's law and closure of the topology under arbitrary union we can see that this intersection always gives a closed set. A set is closed if and only if  $A = \bar{A}$ .

**Lemma 1.1.** *Suppose  $x \in \bar{A}$ , then for every neighborhood of  $x$ ,  $V_x$ , we have that  $V_x \cap A \neq \emptyset$ .*

*Proof.* Let  $x \in \bar{A}$  and suppose for some neighborhood  $V_x$  of  $x$  we have that  $V_x \cap A = \emptyset$ . Then we know that  $V_x^\circ \cap A = \emptyset$ . Take  $\bar{A} = \bar{A} \cap (V_x^\circ)^c$ . We can verify that this is a smaller closed set that also contains  $A$ .  $\square$

**Definition 1.7** (Boundary). The boundary of a set  $A$ , denoted  $\delta A$ , is  $\bar{A} \setminus A^\circ$ .

A useful concept when talking about convergence under a topology is that of a neighborhood of a point  $x \in X$ .

**Definition 1.8** (Neighborhood). For a point  $x \in X$  a set  $V$  is a neighborhood of  $X$  if  $x \in V^\circ$ .

We can now use the topology to define limit points and convergence.

**Definition 1.9** (Limit Point). A point  $x \in X$  is a limit point of a set  $A \subseteq X$  if, for every neighborhood  $V$  of  $x$ ,

$$A \cap (V \setminus \{x\}) \neq \emptyset.$$

In other words, every neighborhood of  $x$  intersects with  $A$  at a point other than  $x$ . Let  $A'$  be the set of all limit points of  $A \subseteq X$ .

**Lemma 1.2.** *If  $S$  is a subset of  $X$ , then  $\bar{S} = S \cup S'$ .*

*Proof.* First show that  $\bar{S} \subseteq S \cup S'$ . Let  $x \in \bar{S}$ . If  $x \in S$  then we are done. Otherwise, suppose  $x \in \bar{S} \setminus S$ . This means that for all  $V_x$  we have that  $S \cap V_x = S \cap (V_x \setminus \{x\})$ . By the result of Lemma 1.1, we have that  $V_x \cap S \neq \emptyset$ . So,  $x \in S'$ .

Now suppose that  $x \in S \cup S'$ . Clearly if  $x \in S$  then  $x \in \bar{S}$ . Suppose then that  $x \in S' \setminus S$  but  $x \notin \bar{S}$ . Let  $\tilde{S}$  be any closed set containing  $S$ , that is  $S \subseteq \tilde{S}$ . For sake of contradiction, suppose that  $x \notin \tilde{S}$  ( $x$  is a limit point of  $S$  that is not in  $\tilde{S}$ ). Because  $\tilde{S}$  is closed we know that  $\tilde{S}^c \in \tau$ . Further, we know that  $x \in \tilde{S}^c$  so that  $\tilde{S}^c$  is a neighborhood of  $x$ . Since  $x$  is a limit point of  $S$ , we know that  $\tilde{S}^c \cap S = \tilde{S}^c \cap S \setminus \{x\} \neq \emptyset$ . However, we also know that  $S \subseteq \tilde{S}$  so we have a contradiction. Therefore, it must be that  $x \in \bar{S}$  which completes the proof.  $\square$

**Lemma 1.3** (Characterization of Closed Sets). *A set is closed if and only if it contains all of its limit points.*

*Proof.* This is a consequence of Lemma 1.2 and the fact that  $A$  is closed if and only if  $\bar{A} = A$ .  $\square$

**Definition 1.10** (Convergence). We say a sequence  $\{x_n\}_{n=1}^\infty$  converges to a point  $x \in X$  if for every neighborhood  $V_x$  of  $x$ , there exists a number  $M$  such that for all  $m \geq M$ ,  $x_m \in V_x$ .

Note that under the trivial topology  $\tau = \{\emptyset, X\}$  all sequences converge to any point  $x \in X$  whereas under the discrete topology on  $\mathbb{R}$ ,  $\tau = 2^{\mathbb{R}}$ , no sequence converges.

**Definition 1.11** (Continuity). Let  $(\mathcal{X}, \tau_1)$  and  $(\mathcal{Y}, \tau_2)$  be two topological spaces and  $f : \mathcal{X} \rightarrow \mathcal{Y}$ . We say  $f$  is continuous if  $f^{-1}(A) \in \tau_1$  for all  $A \in \tau_2$ . That is, a continuous function maps open sets to open sets.

We can now get ready to combine the notions of continuity and convergence coming from a topology with the notions that we are familiar with from metric spaces. First, we need to define the topology generated by a metric.

**Definition 1.12** (Generated Topology). Let  $\mathcal{A}$  be a collection of subsets of  $X$ . The topology generated by  $\mathcal{A}$ ,  $\langle \mathcal{A} \rangle$  is the smallest topology that contains  $\mathcal{A}$ :

$$\langle \mathcal{A} \rangle = \bigcap \{ \tau : \mathcal{A} \subseteq \tau \}.$$

We will then define the topology generated by a metric as the topology generated by the collection of open balls  $B(x, \epsilon)$ .

**Definition 1.13** (Open Ball). Let  $d(x, y)$  be a metric on a vector space  $X$ . For any point  $x \in X$  define the open ball of size  $\epsilon$  around  $x$  as:

$$B(x, \epsilon) = \{y : d(x, y) \leq \epsilon\}.$$

In a metric space, we consider the topology generated by all the open balls  $\tau_d = \langle \{B(x, \epsilon) : x \in X, \epsilon > 0\} \rangle$ . In fact, the set of open balls is a basis for this topology, which means that every open set  $A$  in  $\tau_d$  and any point  $x \in A$ , there is an open ball  $B$  such that  $x \in B \subseteq A$ .<sup>1</sup> Many topological properties such as continuity or convergence can be verified by simply confirming the properties for all members of a basis for the topology. This ties together the “epsilon-delta” notions of continuity and convergence with the more general topological versions given above.

For the rest of this subsection we will talk about separability and compactness, but give examples using normed-metric spaces instead of talking in generality about the topology.

**Definition 1.14** (Dense Subset). A topological space  $(X, \tau)$  has a dense subset  $\mathcal{A}$  if  $\bar{\mathcal{A}} = X$ . Equivalently, by Lemma 1.2, every point of  $X$  is either in  $\mathcal{A}$  or is a limit point of  $\mathcal{A}$ .

Informally, all points in  $X$  are either in  $\mathcal{A}$  or arbitrarily “close” to  $\mathcal{A}$ . As an example, in the standard topology on  $\mathbb{R}$  generated by the metric  $d(x, y) = |x - y|$ , the rationals  $\mathbb{Q}$  are dense. We also have that, for the set of continuous functions under the sup norm, the set of all polynomials is dense, which means that we can approximate a function arbitrarily well with them.

**Definition 1.15** (Seperable Space). We say that a topological space  $(X, \tau)$  is separable if it has a countable dense subset.

As we went over above, the real line with its standard topology is separable. The  $L_p[a, b]$  spaces are also generally separable for  $1 \leq p \leq \infty$ . However  $L_\infty$  is not separable, which will cause issues (this is not the example below).

**Example 1.1** (Bounded functions with the sup norm is not seperable). Let  $\{f_i\}_{i \in \mathbb{N}}$  be a countable set of functions on  $B_\infty[a, b]$ . Let  $\{q_i\}_{i \in \mathbb{N}}$  be some counting of the rational numbers between  $a$  and  $b$ . Let  $\tilde{f}$  be some function that is equal to 0 except on the rational numbers. For each rational number  $q_i$  define

$$\tilde{f}(q_i) = \begin{cases} 1 & \text{if } f_i(q_i) \leq 0 \\ -1 & \text{if } f_i(q_i) > 0 \end{cases}.$$

We can see that  $\tilde{f}$  is bounded (and integrates to 0), but it is at least distance one from each function in  $\{f_i\}_{i \in \mathbb{N}}$ .

Initially I thought this example would work for  $L_\infty[a, b]$ , but this only forces a difference on a set of measure 0 and I believe  $L_\infty$  works with an essential supremum norm.

Another important/useful concept is that of compactness. The general notion is given below:

**Definition 1.16** (Compact Set). A set  $A$  is compact if for every collection of open sets  $\{G_i\}$  such that  $A \subset \bigcup G_i$ , there is a finite subcollection that also covers  $A$ .

**Example 1.2.** The real-line is not compact. Consider the open cover  $\{(n, n + 1) | n \in \mathbb{Z}\}$

**Example 1.3.** The interval  $(0, 1]$  is not compact. Consider the open cover  $\{(1/n, 1 + 1/n) | n \in \mathbb{N}\}$

**Theorem 1.1** (Heine-Borel). For a subset  $S$  of the Euclidean Space<sup>2</sup>,  $\mathbb{R}^n$ , the following statements are equivalent:

- $S$  is closed and bounded

<sup>1</sup>In fact, the set of all open balls with rational  $\epsilon$  is a basis for the topology

<sup>2</sup>That is the space  $\mathbb{R}^n$  equipped by the topology generated by the standard distance metric

- $S$  is compact

Compactness is nice because of various extreme value theorems that ensure that a supremum or infimum is attained. Heine-Borel gives a nice way of characterizing compactness for Euclidean Spaces, but in general there is no equivalent result for general metric spaces. We have to strengthen the boundedness assumption.

**Definition 1.17** (Totally Bounded). A set  $\mathcal{A}$  is totally bounded if for each  $\epsilon > 0$  there exists a finite sequence  $\{a_1, \dots, a_n\}$  such that for  $B_i = \{a \in \mathcal{A} : \|a - a_i\| \leq \epsilon\}$ ,  $\bigcup_{i=1}^n B_i$  covers  $\mathcal{A}$ .

**Intuition:** For any precision  $\epsilon$ , you can find a finite set of points that describe  $\mathcal{A}$  arbitrarily well. (much more demanding in infinite dimensions than just bounded).

**Theorem 1.2.** In a complete metric space, the following are equivalent:

- $\mathcal{A}$  is a compact subset
- $\mathcal{A}$  is closed and totally bounded
- Every sequence in  $\mathcal{A}$  has a convergent subsequence which converges to a point in  $\mathcal{A}$ .

For a compact set  $T$ , let  $C(T)$  be the set of continuous functions from  $T$  to  $\mathbb{R}$  equipped with the sup norm. We may want to characterize when a subset  $K$  of  $C(T)$  is compact.

**Definition 1.18** (Equicontinuous). A set of functions  $K \subseteq C(T)$  is equicontinuous if for every  $t_0 \in T$  and  $\epsilon > 0$  there is a  $\delta > 0$  such that  $|f(t) - f(t_0)| < \epsilon$  whenever  $\|t - t_0\| < \delta$  for all  $f \in K$ .

This is a bit like to uniform continuity but adapted a bit to deal with a function space.

**Theorem 1.3** (Arzela-Ascoli). If  $T$  is compact, then  $K \subseteq C(T)$  is compact (under the sup-norm) if and only if  $K$  is bounded and equicontinuous.

This concludes our discussion of topology and continuity. We now review measurability.

### 1.3 Probability Spaces and Outer Measure

**Definition 1.19** (Sigma Algebra). A collection of subsets  $\mathcal{F}$  is a sigma-algebra (or sigma-field) if it contains the whole set and is closed under complement and under countable union.

**Definition 1.20** (Borel Sigma Algebra). For any collection of sets  $\mathcal{A}$ , we call the smallest sigma algebra containing  $\mathcal{A}$ ,  $\sigma(\mathcal{A})$ , the sigma algebra generated by  $\mathcal{A}$ . The Borel sigma algebra on a topological space is the sigma algebra generated by all the open sets,  $\mathcal{B}(X) = \sigma(\tau)$ .

The Borel sigma algebra is useful as it makes all continuous functions measurable (defined below).

**Definition 1.21** (Probability Space). A probability space is a triple  $(\Omega, \mathcal{F}, \mathbb{P})$  consisting of a set of elements  $\Omega$ , a sigma algebra on  $\Omega$ ,  $\mathcal{F}$ , and a probability measure  $\mathbb{P} : \mathcal{F} \rightarrow [0, 1]$  satisfying:

1.  $\mathbb{P}(A) \geq \mathbb{P}(\emptyset) = 0$  [Non-negativity]
2. If  $A_i \in \mathcal{F}$  is a countable sequence of disjoint sets then  $\mathbb{P}(\bigcup_i A_i) = \sum_i \mathbb{P}(A_i)$
3.  $\mathbb{P}(\Omega) = 1$ .

A measurable function between two spaces equipped with sigma algebra's is simply one that maps measurable sets to measurable sets, similar to the definition of a continuous function.

**Definition 1.22** (Measurable Map). A function  $f : (\mathcal{X}, \mathcal{A}) \rightarrow (\mathcal{Y}, \mathcal{B})$  is measurable if  $f^{-1}(B) \in \mathcal{A}$  for all  $B \in \mathcal{B}$

**Lemma 1.4** (Lemma 1.3.1 VdV& W). The Borel  $\sigma$ -field on a metric space  $\mathbb{D}$  is the smallest  $\sigma$ -field that makes all elements of  $C_b(\mathbb{D})$  measurable (with respect to the Borel sets on  $\mathbb{R}$ ).<sup>1</sup>

<sup>1</sup> $C_b(\mathbb{D})$  is the set of all continuous bounded functions from  $\mathbb{D} \rightarrow \mathbb{R}$ , where  $\mathbb{R}$  is endowed with the standard topology on the real line

*Proof.* For any closed set  $F$ ,  $F$  is the null set  $\{x : f(x) = 0\}$  of the continuous, bounded function,  $x \mapsto d(x, F) \wedge 1$ . Since the singleton  $\{0\}$  is a closed set in  $\mathbb{R}$  (all metric spaces are Hausdorff),  $F$  must be in the sigma algebra on  $\mathbb{D}$  to make  $d(x, F) \wedge 1$  measurable. Since all the closed sets generate the Borel  $\sigma$ -field (because  $\sigma$ -fields are closed under complement), all Borel sets must be included in the sigma-algebra on  $\mathbb{D}$ .  $\square$

Given this, we can abstractly think about a random variable as a measurable map from a probability space into another measurable space (typically the real-line). Measurability ensures that things like expectations and probabilities of random variables are well defined.

However, measurability becomes a problem when we are dealing with random functions. For example, if  $X$  is a map from a probability space to  $L_\infty[a, b]$ , the Borel-sigma algebra on  $L_\infty[a, b]$  is quite large (its not separable). This means that measurable sets in  $L_\infty[a, b]$  may not map back to measurable sets on the probability space  $\Omega, \mathcal{F}, \mathbb{P}$ .

This is a problem because  $L_\infty$  is typically a useful space to work in for empirical process theory. So we have to find a way to relax measurability. This means that we work with outer expectations and probabilities:

**Definition 1.23** (Outer Measure and Inner Measure). Let  $(\Omega, \mathcal{F}, \mathbb{P})$  be a probability space  $T : \Omega \rightarrow \mathbb{R}$ . Define the outer expectation:

$$\mathbb{E}^*[T] = \inf \{ \mathbb{E}[U] : T \leq U, U \text{ is measurable} \}.$$

and the inner expectation:

$$\mathbb{E}_*[T] = \sup \{ \mathbb{E}[U] : U \leq T, U \text{ is measurable} \}.$$

We can use this to define inner and outer probability measures by restricting  $T$  to be the indicator function for an arbitrary set  $B$ . Inner and outer expectations are generally nicely behaved but they require modified versions of dominated and monotone convergence and Fubini's theorem breaks down.

## 2 Weak Convergence

### 2.1 Definition and Characterizations

We can now talk about weak convergence of random variables. Let  $X_n$  be a real-valued random variable with cdf  $F_n(t)$  and let  $X$  be a random variable with cdf  $F(t)$ . The typical definition of weak convergence is that  $X_n \xrightarrow{L} X$  if  $F_n(t) \rightarrow F(t)$  pointwise at all continuity points of  $F$ . This is not super general for non-real valued random maps.

**Theorem 2.1** (Portmanteau). *For real random variables  $X_n \xrightarrow{L} X$  is equivalent to:*

- $\mathbb{E}[g(X_n)] \rightarrow \mathbb{E}[g(X)]$  for all bounded continuous functions.
- For all open sets  $G$ ,  $\liminf \mathbb{P}(X_n \in G) \geq \mathbb{P}(X \in G)$ .
- For all closed sets  $K$ ,  $\limsup \mathbb{P}(X_n \in K) \leq \mathbb{P}(X \in K)$ .

This motivates the theory of weak convergence for general metric spaces. Let  $\mathbb{D}$  be a complete metric space with metric  $d$ . We can equip  $\mathbb{D}$  with it's Borel-sigma algebra as defined in Definition 1.20 and a tight probability measure as defined in Definition 2.1. Let  $C_b(\mathbb{D})$  be the set of all continuous and bounded real functions on  $\mathbb{D}$ . If  $X$  is a random variable,  $X : (\Omega, \mathcal{F}, \mathbb{P}) \rightarrow \mathbb{D}$  then it's law is given  $L = \mathbb{P} \circ X^{-1}$ .

**Definition 2.1** (Tight Probability Measure). A probability measure is tight if for every  $\epsilon > 0$  there is a compact set  $K_\epsilon$  such that  $\mathbb{P}(K_\epsilon) \geq 1 - \epsilon$

This is a generalization of bounded in probability I believe.

**Definition 2.2** (Borel Law). For a random variable  $X$ , we say that  $X$  has a Borel Law  $L$  if

$$\mathbb{P}(X \in A) = \int_A dL.$$

for all Borel sets  $A$ .

Given this setup, we can now define weak convergence:

**Definition 2.3** (Weak Convergence). Let  $(\Omega_n, \mathcal{F}_n, \mathbb{P}_n)$  be a sequence of probability spaces and  $X_n : \Omega_n \rightarrow \mathbb{D}$ . Then we say that  $X_n \xrightarrow{L} X$  if:

$$\mathbb{E}^* [f(X_n)] \rightarrow \mathbb{E}[f(X)].$$

for every  $f \in C_b(\mathbb{D})$

We can characterize this convergence using another Portmanteau theorem.

**Theorem 2.2** (Portmanteau). *The following are equivalent:*

1.  $X_n \xrightarrow{L} X$
2.  $\liminf \mathbb{P}_*(X_n \in G) \geq \mathbb{P}(X \in G)$  for all open sets  $G$ .
3.  $\limsup \mathbb{P}^*(X_n \in F) \leq \mathbb{P}(X \in F)$  for every closed set  $F$ .
4.  $\lim P(X_n \in B) = P(X \in B)$  for every Borel set  $B$  with  $P(X \in \delta B) = 0$ .

**Question:** Is  $X$  supposed to have a Borel Law? Otherwise where do open and closed sets get tied into this? Is it from the notion of convergence?

*Proof.* This proof is in a few steps.

(4)  $\implies$  (3): Suppose that  $\lim P(X_n \in B) = P(X \in B)$  for every Borel set  $B$  with  $\mathbb{P}(X \in \delta B) = 0$ . Let  $F$  be a closed set and let  $F^\epsilon = \{x : d(x, F) < \epsilon\}$ . The sets  $\delta F^\epsilon$  are disjoint for different values of  $\epsilon > 0$  (The boundary of this set is  $\delta F^\epsilon = \{x : d(x, F) = \epsilon\}$ ), so at most countably many of them can have nonzero L-measure (otherwise the measure of the entire space would be infinite). Choose a sequence  $\epsilon_m \downarrow 0$  with  $L(\delta F^{\epsilon_m}) = 0$  for each  $m$  (this is possible because only countably many  $\epsilon$  have  $L(F^\epsilon) \neq 0$ ). For a fixed  $m$ , by (4) we have that:

$$\limsup P^*(X_n \in F) \leq \limsup P^*(X_n \in \overline{F^{\epsilon_m}}) = L(\overline{F^{\epsilon_m}}).$$

letting  $m \rightarrow \infty$  gives (3).

(3)  $\iff$  (2): Take any closed set  $F$ . Its complement  $F^c$  is open. If

$$\liminf \mathbb{P}_*(X_n \in F^c) \geq \mathbb{P}(X \in F^c).$$

Then

$$\begin{aligned} \limsup \mathbb{P}^*(X_n \in F) &\leq \liminf 1 - \mathbb{P}_*(X_n \in F^c) \\ &\leq 1 - \mathbb{P}(X \in F^c) \\ &= \mathbb{P}(X \in F) \end{aligned}$$

a symmetric argument shows the backwards direction.

(2)+(3)  $\implies$  (4): This is straightforward if we recall that, for any set with  $L(\delta B) = 0$  we have that  $L(B) = L(\bar{B})$ . Then we bound the  $\limsup$  by the  $\liminf$ :

$$\limsup \mathbb{P}^*(X \in B) \leq \limsup \mathbb{P}(X \in \bar{B}) \leq \mathbb{P}(X \in \bar{B}) = \mathbb{P}(X \in B) \leq \liminf \mathbb{P}_*(X_n \in B).$$

which gives (4).

(1)  $\implies$  (2): Take any  $G$  open and define the sequence of functions:

$$f_m(x) := \min(1, m \cdot d(x, G^c))$$

Notice that  $f_m(x) \in C_b(\mathbb{D})$  and  $f_m(x) \leq \mathbf{1}\{x \in G\}$ . So, for every  $m$  we have that

$$\begin{aligned} \liminf \mathbb{P}_*(X \in G) &= \liminf \mathbb{E}_* [\mathbf{1}\{X \in G\}] \\ &\geq \liminf \mathbb{E}_* [f_m(X)] \\ &\geq \mathbb{E}[f_m(X)] \end{aligned}$$

since  $f_m(x) \uparrow \mathbf{1}\{X \in G\}$  by monotone convergence we get the result in (2).

**Question:** How do we know from weak convergence that this sequence converges in inner expectation?

By VdV and Wellner, weak convergence implies (is equivalent to)  $\liminf \mathbb{E}_* [f(X_n)] \geq \mathbb{E} [f(X)]$  for every bounded, Lipschitz continuous, non-negative  $f$ . I think the argument for why this is the case goes: Let  $f \geq 0$  be bounded and continuous. Then by weak convergence

$$\limsup \mathbb{E}^*[-f(X_n)] = \mathbb{E}[-f(X)].$$

Taking negatives will give:

$$\liminf \mathbb{E}_*[f(X_n)] \geq -\limsup \mathbb{E}^*[-f(X_n)] = \mathbb{E}[f(X)].$$

In any case,  $f_m(X)$  is Lipschitz continuous which gives the result.

(2)  $\implies$  (1): (SKETCH)

- Suppose  $f(x) \geq 0$  is continuous and bounded
- Approximate it from above and below by indicator functions of open sets.

□

Weak convergence is nice because it gives the continuous mapping theorem.

**Theorem 2.3** (Continuous Mapping Theorem). *Let  $g : \mathbb{D} \rightarrow \mathbb{E}$  be continuous at every point  $\mathbb{D}_0 \subseteq \mathbb{D}$ . If  $X_n \xrightarrow{L} X$  and  $\mathbb{P}(X \in \mathbb{D}_0) = 0$  then  $g(X_n) \xrightarrow{L} g(X)$ .*

*Proof.* (Without Discontinuity Points): Let  $Z_n = g(X_n)$  and  $Z = g(X)$ . We want to show that  $\mathbb{E}^* [f(Z_n)] \rightarrow \mathbb{E} [f(Z)]$  for all  $f \in C_b(\mathbb{D}; \mathbb{E})$ .

$$\lim_{n \rightarrow \infty} \mathbb{E}[f(Z_n)] = \lim_{n \rightarrow \infty} \mathbb{E}[f(g(X_n))] = \mathbb{E}[f(g(X))] = \mathbb{E}[f(Z)].$$

The main step here is weak convergence of  $X_n$  and the stability of  $C_b(\mathbb{D}; \mathbb{E})$  under composition.

(With Discontinuity Points, from VdV&W): The set  $D_g$  of all points at which  $g$  is discontinuous can be written

$$D_g = \bigcup_{m=1}^{\infty} \bigcap_{k=1}^{\infty} \{x : \exists y, z \in B(x, 1/k) \text{ with } d_{\mathbb{E}}(g(y), g(z)) > 1/m\}.$$

*Intuition:* Recall that  $g$  is continuous at  $x$  if for every  $m \in \mathbb{N}$  there exists a  $k \in \mathbb{N}$  such that<sup>1</sup>

$$y, z \in B(x, 1/k) \implies d_{\mathbb{E}}(g(y), g(z)) < 1/m$$

If the function is not continuous at  $x$  you can find a counterexample for some  $k, m \in \mathbb{N}$ .

<sup>1</sup>Topologically, this is saying that the inverse map of every open neighborhood of  $f(x)$  is an open neighborhood of  $x$

Let  $G_k^m = \{x : \exists y, z \in B(x, 1/k) \text{ with } d_{\mathbb{E}}(g(y), g(x)) > 1/m\}$ . Every  $G_k^m$  is open (if  $x$  is in  $G_k^m$  the points just around  $x$  will be as well so that we can write  $G_k^m$  as a union of open balls) so that  $D_g$  is a Borel set. For every closed  $F$  we then have that:

$$\overline{g^{-1}(F)} \subseteq g^{-1}(F) \cup D_g.$$

By Portmanteau:

$$\begin{aligned} \limsup \mathbb{P}^*(g(X_n) \in F) &\leq \limsup P^*(X_n \in \overline{g^{-1}(F)}) \leq \mathbb{P}(X \in \overline{g^{-1}(F)}) \\ &= \mathbb{P}(X \in g^{-1}(F)) \\ &= \mathbb{P}(g(X) \in F) \end{aligned}$$

Applying Portmanteau again gives weak convergence. □

**Example 2.1.** Take  $\mathbb{G}_n \in L^\infty(\mathbb{R})$ :

$$\mathbb{G}_n(t) := \frac{1}{\sqrt{n}} \sum_{i=1}^n \left( \mathbb{1}\{X_i \leq t\} - \mathbb{E}[\mathbb{1}\{X \leq t\}] \right)$$

and suppose that  $\mathbb{G}_n \xrightarrow{L} \mathbb{G}$  where  $\mathbb{G}$  is some other element of  $L^\infty(\mathbb{R})$ . Let  $Z : L^\infty(\mathbb{R}) \rightarrow \mathbb{R}$  be defined as:

$$Z(f) := \sup_t |f(t)|.$$

this function is continuous. Applying the continuous mapping theorem to  $Z$  allows us to build uniform confidence intervals.

Let  $\gamma_{1-\alpha}$  be the  $1 - \alpha$  quantile of  $Z := \sup_t |\mathbb{G}(t)|$  and construct a confidence interval (at each  $t$ ):

$$\left[ \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\} - \gamma_{1-\alpha}/\sqrt{n}, \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\} + \gamma_{1-\alpha}/\sqrt{n} \right].$$

Then:

$$\begin{aligned} \mathbb{P} \left( \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\} - \gamma_{1-\alpha}/\sqrt{n} \leq \mathbb{E}[\mathbb{1}\{X \leq t\}] \leq \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\} + \gamma_{1-\alpha}/\sqrt{n} : \text{ for all } t \right) \\ = \mathbb{P} \left( |\mathbb{G}_n(t)| \leq \gamma_{1-\alpha} \forall t \right) \\ = \mathbb{P} \left( \sup_t |\mathbb{G}_n(t)| \leq \gamma_{1-\alpha} \right) \end{aligned}$$

But by continuous mapping theorem and Portmanteau, if  $\mathbb{P}(\sup_t |\mathbb{G}| = \gamma_{1-\alpha}) = 0$ :

$$\lim_{n \rightarrow \infty} \mathbb{P} \left( \sup_t |\mathbb{G}_n(t)| \leq \gamma_{1-\alpha} \right) = \mathbb{P} \left( \sup_t |\mathbb{G}(t)| \leq \gamma_{1-\alpha} \right) = 1 - \alpha.$$

This sort of argument can be applied more generally to functions  $\mathbb{G}_n(t) = \hat{m}(t) - m(t)$  to construct uniform confidence intervals.

This shows the usefulness of Portmanteau and Continuous Mapping Theorem. For finite dimension vectors we can use the central limit theorem to establish weak convergence to a normal distribution. However, when  $X_n$  is a random element in  $L^\infty$  it may be harder to show that  $X_n \rightsquigarrow X$  for some other  $X \in L^\infty$ .

- Don't want to check  $\mathbb{E}[f(X_n)] \rightarrow \mathbb{E}[f(X)]$  for all  $f \in C_b(L^\infty)$  [There are at least 20 functions in this class]

Instead we will try to use the structure of  $L^\infty$  to show the result.

**Definition 2.4** (Asymptotic Tightness). A sequence  $X_n$  of random maps is asymptotically tight if for every  $\epsilon, \delta > 0$  there is a compact  $K_\epsilon$  such that

$$\liminf P_\star \left( X_n \in K_\epsilon^\delta \right) \geq 0.$$

where  $K_\epsilon^\delta = \{y \in \mathbb{D} : d(y, K_\epsilon) < \delta\}$  is the “ $\delta$ -enlargement” around  $K_\epsilon$ .

**Definition 2.5** (Asymptotic Measurability). A sequence  $X_n$  of random maps is asymptotically measurable if for all  $f \in C_b(\mathbb{D})$  :

$$\mathbb{E}^\star f(X_n) - \mathbb{E}_\star f(X_n) \rightarrow 0.$$

We would like for a sequence  $X_n$  that weakly converges to an element  $X$  to inherit some properties from  $X$ :

**Lemma 2.1** (Lemma 1.3.8 VdV& W). *The following are true:*

1. If  $X_n \xrightarrow{L} X$  then  $X_n$  is asymptotically measurable
2. If  $X_n \xrightarrow{L} X$  then  $X_n$  is asymptotically tight if and only if  $X$  is tight.

*Proof.* (1): Take any function  $f \in C_b(\mathbb{D})$ . By definition of weak convergence we know that

$$\lim \mathbb{E}^\star [f(X_n)] = \mathbb{E}[f(X)] \quad \text{and} \quad \lim \mathbb{E}^\star [-f(X_n)] = \mathbb{E}[-f(X)].$$

I think we should have that  $-\mathbb{E}_\star [f(X_n)] \geq \mathbb{E}^\star [-f(X_n)]$  for any  $f$  which give the result (I think this holds with equality but I leave it as an inequality since this is all we need for the result).

(2): Fix  $\epsilon > 0$ . If  $X$  is tight then there is a compact  $K$  with  $\mathbb{P}(X \in K) > 1 - \epsilon$ . By Portmanteau:

$$\liminf \mathbb{P}_\star(X_n \in K^\delta) \geq \mathbb{P}(X \in K^\delta).$$

which is larger than  $1 - \epsilon$  for every  $\delta > 0$ .

Conversely, suppose that  $X_n$  is asymptotically tight. Then there exists a compact  $K$  with  $\liminf P_\star(X_n \in K^\delta) \geq 1 - \epsilon$ . By Portmanteau,

$$1 - \epsilon \leq \liminf \mathbb{P}_\star(X_n \in K^\delta) \leq \limsup \mathbb{P}^\star(X_n \in \overline{K^\delta}) \leq \mathbb{P}(X \in \overline{K^\delta}).$$

Let  $\delta \rightarrow 0$  by monotone convergence to complete the result. <sup>2</sup> □

The converse is not generally true. Let  $X_n = -1$  if  $n$  is odd and  $X_n = 1$  if  $n$  is even. This sequence is asymptotically measurable and asymptotically tight but clearly does not converge. However, it does converge among a subsequence. This is the idea behind the partial converse to this theorem provided by Pohorov's Theorem.

**Theorem 2.4** (Pohorev's Theorem, Theorem 1.3.9 VdV& W). *Let  $X_n$  be an asymptotically tight and asymptotically measurable sequence. Then there is a subsequence  $X_{n_j}$  that converges weakly to a tight Borel law.*

Now a review problem

**Example 2.2** (Problem 7; Ch 1.3 VdV& W). Let  $X_n$  be a sequence of random elements in  $\mathbb{D}$  and  $g : \mathbb{D} \rightarrow \mathbb{E}$  a continuous function. Want to show that:

<sup>2</sup>This proof relies on compact sets being closed in metric spaces. The proof of this is as follows: Let  $A$  be compact in a metric space. We wish to show that  $A$  is closed. Take a point  $x \in X \setminus A$ . To show that  $A$  is closed, we want to show that there is an open neighborhood of  $x$  that is not in  $A$  (this will show that  $A$  contains all of its limit points). For every  $a \in A$ , let  $U_a = B\left(a, \frac{d(a,x)}{2}\right)$  and  $V_a = B\left(x, \frac{d(a,x)}{2}\right)$ . By triangle inequality,  $U_a$  and  $V_a$  are disjoint. The union of all the sets  $U_a$  for all points  $a \in A$  is an open cover of  $A$ . By compactness of  $A$ , we can get a finite subcover  $U_{a_1}, \dots, U_{a_n}$ . But then  $V_{a_1} \cap \dots \cap V_{a_n}$  is an open neighborhood of  $x$  that is disjoint from  $A$ . So  $A$  is closed. Actually this argument holds in general Hausdorff spaces.

1. If  $X_n$  is asymptotically tight then  $g(X_n)$  is asymptotically tight.
2. If  $X_n$  is asymptotically measurable then  $g(X_n)$  is asymptotically measurable.

*Proof.* 1) Suppose that  $X_n$  is asymptotically tight. Fix  $\epsilon > 0$ . We know that there exists a compact set  $K$  such that,  $\forall \delta_1 > 0$

$$\liminf \mathbb{P}_\star \left( X_n \in K^{\delta_1} \right) \geq 1 - \epsilon.$$

The event  $\{X_n \in K^{\delta_1}\}$  is a subset of the event that  $\{g(X_n) \in g(K^{\delta_1})\}$  so

$$\liminf \mathbb{P}_\star \left( g(X_n) \in g(K^{\delta_1}) \right) \geq \liminf \mathbb{P}_\star \left( X_n \in K^{\delta_1} \right) \geq 1 - \epsilon.$$

To finish recall that  $g(K)$  is a compact set and choose  $\delta_1$  such that  $g(K^{\delta_1}) \subseteq g(K)^\delta$  (always possible to do so by continuity of  $g$ ).

2) Suppose that  $X_n$  is asymptotically measurable. This means that, for any  $f \in C_b(\mathbb{D})$ :

$$\mathbb{E}^\star [f(X_n)] - \mathbb{E}_\star [f(X_n)] \rightarrow 0.$$

Let  $\tilde{f} \in C_B(\mathbb{E})$ . For any continuous  $g : \mathbb{D} \rightarrow \mathbb{E}$ ,  $\tilde{f} \circ g$  is a continuous and bounded function from  $\mathbb{D} \rightarrow \mathbb{R}$ . This completes the proof.  $\square$

## 2.2 Weak Convergence in Space of Bounded Functions

So far, we have defined weak convergence. But, how do we show that  $X_n \xrightarrow{L} X$ ? In  $\mathbb{R}^K$  we have the central limit theorem, but no direct analog for random maps into  $L^\infty$ .

First, some definitions.

**Definition 2.6** (Marginal Random Variable). Let  $X_n$  be a random map into  $L^\infty(T)$  (the space of all bounded functions from  $T \rightarrow \mathbb{R}$ ). Then,  $X_n(t)$  is the marginal distribution of  $X_n$  at  $t$ . We can view  $X_n(t)$  as the composition of  $X_n$  with  $\pi_t$  or directly as a real-valued random variable.

A general strategy will be to deal with the marginals directly. By the central limit theorem, we have conditions for the weak convergence of  $X_n(t)$ . Want to know what these results imply for the random map  $X_n$ .

**Lemma 2.2** (Lemma 1.5.1, VdV&W). *Let  $X_n : \Omega \rightarrow L^\infty(T)$  be asymptotically tight. Then it is asymptotically measurable if and only if  $X_n(t)$  is asymptotically measurable for every  $t \in T$ .*

**Lemma 2.3** (Lemma 1.5.3, VdV&W). *Let  $X$  and  $Y$  be tight Borel measurable maps into  $L^\infty(T)$ . Then  $X \stackrel{L}{=} Y$  if and only if  $X(t) \stackrel{L}{=} Y(t)$  for all  $t \in T$ .*

**Theorem 2.5** (Theorem 1.5.4, VdV&W). *Let  $X_n : \Omega_n \rightarrow L^\infty(T)$  be arbitrary. Then  $X_n$  weakly converges to a tight limit if and only if  $X_n$  is asymptotically tight and the marginals  $(X_n(t_1), \dots, X_n(t_k))$  converge weakly to a limit for every finite subset  $t_1, \dots, t_k$ .*

*Proof.* Forward direction is simple, backwards direction requires more work:

( $\implies$ ) Suppose that  $X_n \xrightarrow{L} X$  and  $X$  is tight. By Lemma 2.1, this means that  $X_n$  is asymptotically tight. Let  $T_k : L^\infty(T) \rightarrow \mathbb{R}^k$  be the projection onto the coordinates  $t_1, \dots, t_k$ . This is a continuous function so by continuous mapping theorem we have convergence of the marginals for any finite collection.

( $\impliedby$ ) Suppose that  $X_n$  is asymptotically tight and the marginals converge. Then, by Lemma 2.2,  $X_n$  is asymptotically measurable. By Pohorov's theorem, there is a subsequence  $X_{n_k} \xrightarrow{L} X$  for some  $X$ . Suppose  $X_n \not\xrightarrow{L} X$ . Then, there is a subsequence  $X_{n'_k}$  that stays away from  $X$  (in law). However, the marginals converge. This means that the marginals of  $Y$  are the same as the marginals of  $X$ . By Lemma 2.3,  $X \stackrel{L}{=} Y$ .  $\square$

### Intuition: Why is Tightness + Convergence of Marginals Enough?

- Tightness:  $P(X \in K) \geq 1 - \epsilon$  for some compact set  $K$ .
  - In a metric space, compact means for any  $\epsilon > 0$  there are a finite set of points that approximate the whole set well.
  - \* But! For a finite set of points we have convergence of marginals

Showing convergence of marginal distributions is straightforward by CLT. Next, we cover how to show tightness. Then Theorem 2.5 gives convergence of the entire process. To verify tightness we want a better description than the definition of asymptotic tightness. Two approaches

1. Finite Approximation  $\rightarrow$  simpler
2. Arzela-Ascoli Theorem  $\rightarrow$  larger interest (asymptotic equicontinuity)

#### 2.2.1 Finite Approximation

The general idea here is that, for any  $\epsilon > 0$ , we can partition the index set  $T$  (as in  $\ell^\infty(T)$ ) into a finite number of sets  $T_i$  so that the variation in each set is  $< \epsilon$ . Formally, for any  $\eta > 0$ ,

$$\limsup_{n \rightarrow \infty} \mathbb{P} \left( \max_i \sup_{s, t \in T_i} |X_n(s) - X_n(t)| > \epsilon \right) < \eta.$$

### Intuition: Why should we expect this to work?

- Tightness means that you concentrate on a compact set
  - Compact set is well described by a finite # of functions

**Theorem 2.6** (Theorem 1.5.6 VdV&W). *A sequence of random maps  $X_n \in \ell^\infty(T)$  is asymptotically tight if and only if  $X_n(t)$  is asymptotically tight in  $\mathbb{R}$  for every  $t$  and, for all  $\epsilon, \eta > 0$  there is a partition  $T = \cup_{i=1}^n T_i$  such that*

$$\limsup_{n \rightarrow \infty} \mathbb{P}^* \left( \max_i \sup_{s, t \in T_i} |X_n(s) - X_n(t)| > \epsilon \right) < \eta \quad (\text{FA-1})$$

*Proof.* Cover sufficiency. Necessity follows from Theorem 1.5.7 in Van Der Vaart and Wellner. Suppose that (FA-1) holds. Fix  $\epsilon > 0$  and let the partition  $T = \bigcup_{i=1}^k T_i$  satisfy (FA-1) for some  $\eta > 0$ . We want to show that  $\sup_t |X_n(t)|$  is asymptotically tight. Then:

$$\begin{aligned} \limsup \mathbb{P}^* \left( \sup_{t \in T} |X_n(t)| > M \right) &\leq \limsup \mathbb{P}^* \left( \sup_{t \in T} > M, \text{ and (FA-1) holds} \right) \\ &\quad + \limsup \mathbb{P}^* \left( \text{(FA-1) doesn't hold} \right) \\ &\leq \limsup \mathbb{P}^* \left( \max_{1 \leq i \leq k} |x_n(t_i)| + \epsilon > M \right) + \eta \end{aligned}$$

Where in the last line we use the bounded variation within each set  $T_i$  and pick some arbitrary elements  $t_i \in T_i$ . Now note that each  $X_n(t_i)$  is asymptotically tight by assumption so that  $\max_{1 \leq i \leq k} |X_n(t_i)|$  is asymptotically tight.<sup>1</sup> This means that we can pick  $M$  so that

$$\limsup \mathbb{P}^* \left( \sup_t |X_n(t)| > M \right) < \eta.$$

---

<sup>1</sup>Couple of quick arguments to get this one:

1. If each  $X_{i,n}$  in  $\{X_{i,n}\}_{i=1}^K$  is asymptotically tight then the vector  $[X_1 \dots X_K]$  is asymptotically tight. This is because the Cartesian product of a finite number of compact sets is compact (with respect to the product topology).
2. If  $X_n$  is asymptotically tight and  $g$  is a continuous function then  $g(X_n)$  is asymptotically tight. This is shown in Example 2.2 and basically follows from the fact that a continuous function applied to a compact set yields a compact set. The maximum operator is continuous.

or, to put this another way, for every  $\eta > 0$  we can show that there is an  $M$  such that:

$$\limsup \mathbb{P}^* \left( \sup_t |X_n(t)| > M \right) < \eta.$$

So we have shown that  $\sup_t |X_n(t)|$  is bounded in probability. Since  $\sup_t |X_n(t)|$  is a map onto the real line, bounded in probability coincides with asymptotic tightness (Heine-Borel).

Now we want to construct a candidate compact set  $K$  for the process  $X_n$ . Fix  $\zeta > 0$  and a sequence  $\epsilon_n \downarrow 0$ . First, pick an  $M$  such that

$$\limsup_{n \rightarrow \infty} \mathbb{P}^* \left( \sup_t |X_n(t)| > M \right) < \zeta.$$

we know such an  $M$  exists by the above argument. For each  $\epsilon_m$  partition  $T = \bigcup_{i=1}^{K(m)} T_i$  such that

$$\limsup_{n \rightarrow \infty} \mathbb{P}^* \left( \sup_{1 \leq i \leq K(m)} \sup_{s, t \in T_i} |X_n(s) - X_n(t)| > \epsilon_m \right) < \frac{\zeta}{2^m}.$$

For each  $\epsilon_m$  let  $\{z_1, \dots, z_{p(m)}\}$  be the set of functions in  $\ell^\infty(T)$  that are constant on  $T_i$  and only take values  $0, \pm\epsilon_m, \pm 2\epsilon_m, \dots, M$ . It is only important for now that, for any  $m$ ,  $p(m)$  is finite (though large). Let

$$K_m = \bigcup_{i=1}^{p(m)} \bar{B}(z_i, \epsilon_m).$$

where  $\bar{B}(z_i, \epsilon_m)$  is the closed ball of radius  $\epsilon_m$  around  $z_i$ . Note that if  $\sup_t |X_n(t)| \leq M$  and

$$\sup_{1 \leq i \leq p(m)} \sup_{s, t \in T_i} |X_n(s) - X_n(t)| \leq \epsilon_m$$

then  $X_n \in K_m$ . Let  $K = \bigcap_{m=1}^{\infty} K_m$ . Then  $K$  is closed and totally bounded. Closure follows because each  $K_m$  is closed (finite union of closed sets) and an arbitrary intersection of closed sets is closed (because the arbitrary union of open sets is open). To see totally bounded fix  $\delta > 0$ . Then for each  $\epsilon_m < \delta$  we have that  $K_m = \bigcup_{i=1}^{p(m)} \bar{B}(z_i, \epsilon_m)$ . Since  $K_m \supset K$  these balls cover  $K$ .

We now have a candidate  $K$ . We now want to show that, for every  $\delta > 0$ ,  $K^\delta \supset \bigcap_{i=1}^m K_i$  for some  $m$ . Suppose not. Then there is a sequence  $\{z_m\}$  with  $z_m \notin K^\delta$  and  $z_m \in \bigcap_{i=1}^m K_i$  for every  $m$ .<sup>2</sup> This sequence has a subsequence contained in one of the balls making up  $K_1$ , this subsequence in one of the balls in  $K_1$  has a further subsequence contained in one of the balls making up  $K_2$ , that subsequence contains a subsequence eventually contained in  $K_3$ , and so on.<sup>3</sup> Consider the “diagonal” sequence formed by taking the first element of the first subsequence, the second element of the second sequence, and so on. Eventually, this would be contained in a ball of radius  $\epsilon_m$  for any  $m$ .<sup>4</sup> Because  $\epsilon_m \downarrow 0$  this means the sequence is Cauchy. Since  $\ell^\infty(T)$  is a complete (Banach) space this sequence converges and must converge to an element in  $K$ . This contradicts the fact that  $d(z_m, K) \geq \delta$  for every  $m$ .

Finally, combining our previous results, we want to show that  $\liminf \mathbb{P}_*(X_n \in K^\delta) \geq 1 - 2\zeta$ . for every  $\delta > 0$ . This is equivalent to saying that  $\limsup \mathbb{P}^*(X_n \notin K^\delta) < 2\delta$ . Recall that

$$\sup_t |X_n(t)| \leq M \quad \text{and} \quad \sup_i \sup_{s, t \in T_i} |X_n(s) - X_n(t)| \leq \epsilon_m \implies X_n \in K_m.$$

<sup>2</sup>Pick  $z_m \in \bigcap_{i=1}^m K_i \setminus K^\delta$

<sup>3</sup>Why? Each  $\{z_m\}$  is in  $\bigcap_{i=1}^m K_i$ . Fix some  $n$ , then eventually the sequence is contained in  $\bigcap_{i=1}^n K_n$  and so is contained in  $K_n$  since  $K_n \supset \bigcap_{i=1}^n K_n$ . This means the sequence  $\{z_m\}$  has infinite members in  $K_n$ .  $K_n$  is the union of a finite number of sets, so one of these sets must contain infinite members

<sup>4</sup>Key here is the boundedness of the functions we are considering.

Then, to show asymptotic tightness:

$$\begin{aligned}
\limsup_{n \rightarrow \infty} \mathbb{P}^* \left( X_n \notin \bigcup_{i=1}^n K_i \right) &\leq \limsup \mathbb{P}^* \left( X_n \notin \bigcup_{i=1}^m K_i; \sup_t |X_n(t)| \leq M \right) + \underbrace{\limsup \mathbb{P}^* \left( \sup_t |X_n(t)| > M \right)}_{< \zeta} \\
&\leq \limsup \mathbb{P}^* \left( \sup_i \sup_{s, t \in T_i} |X_n(s) - X_n(t)| > \epsilon_m \text{ for some } m \right) + \zeta \\
&\leq \sum_{j=1}^m \limsup \mathbb{P}^* \left( \sup_i \sup_{s, t \in T_i} |X_n(s) - X_n(t)| > \epsilon_j \right) + \zeta \\
&\leq \sum_{j=1}^m \frac{\zeta}{2^j} + \zeta \\
&< 2\zeta
\end{aligned}$$

□

Proof is involved but useful as it shows the equivalence between asymptotic tightness and a finite approximation notion. The proof also builds some intuition for why tightness is important, at each step we are essentially showing that the whole behavior of the set is well describes (up to a tolerance of size  $\epsilon$ ) by a finite set of marginals. Weak convergence of the marginals is much easier to show.

This being said, the condition in Theorem 2.6 is hard to check. In particular, there is no guidance given on how to select the partition  $\{T_i\}_{i=1}^m$ . The next way to characterize tightness builds on asymptotic equicontinuity. The idea is the correct way to pick the partition is linked to some form of continuity: pick small  $T_i$  so that  $X_n$  does not move much on  $T_i$ .

**Definition 2.7** (Asymptotic  $\rho$ -equicontinuity in probability). Suppose  $\rho$  is a semimetric on  $T$ . Then a sequence of maps  $X_n : \Omega_n \rightarrow \ell^\infty(T)$  is asymptotically  $\rho$ -equicontinuous if for every  $\epsilon, \eta > 0$  there exists a  $\delta > 0$  such that

$$\limsup_{n \rightarrow \infty} \mathbb{P}^* \left( \sup_{d(s, t) < \delta} |X_n(s) - X_n(t)| > \epsilon \right) < \eta.$$

**Remark.** This is basically setting  $T_i = \{(s, t) : \rho(s, t) < \delta\}$

**Example.** Let  $X_n(t) = \frac{1}{\sqrt{n}} \sum_{i=1}^n [\mathbb{1}\{X_i \leq t\} - \mathbb{P}(X \leq t)]$ . Then  $|X_n(t) - X_n(t')| \approx 0$  for all  $|t - t'| < \delta$ . Note that here, for every  $n$ ,  $X_n(t)$  is still a discontinuous function of  $t$ , it's just that the jumps get closer together or smaller.

**Example.** Suppose that  $\gamma = g(X, \beta_0) + \epsilon$  with  $\mathbb{E}[\epsilon|X] = 0$ . By the vector LLN, we can say that  $\hat{\beta} - \beta_0 \rightarrow_p 0$ .

In contrast, *asymptotic equicontinuity* will allow to say that:

$$\hat{\beta} \rightarrow_p \beta_0 \implies \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \left\{ \left( g(x_i, \hat{\beta}) - \mathbb{E}[g(x, \hat{\beta})] \right) - \left( g(x_i, \beta_0) - \mathbb{E}[g(x, \beta_0)] \right) \right\} \right| = o_p(1).$$

which is a more powerful result.

**Theorem 2.7** (Theorem 1.5.7 Vdv&W). A sequence of random maps,  $X_n : \Omega_n \rightarrow \ell^\infty(T)$  is asymptotically tight if and only if  $X_n(t)$  is asymptotically tight in  $\mathbb{R}$  for each  $t$  and there exists a semimetric  $\rho$  on  $T$  such that  $(T, \rho)$  is totally bounded and  $X_n$  is asymptotically uniformly  $\rho$ -equicontinuous.

*Proof.* First prove sufficiency then necessity:

( $\Leftarrow$ ) Fix  $\epsilon, \eta > 0$ . Then, there is a  $\delta > 0$  such that

$$\limsup \mathbb{P}^* \left( \sup_{\rho(s,t) < \delta} |X_n(s) - X_n(t)| > \epsilon \right) < \eta.$$

Since  $T$  is totally bounded, then there are finitely many balls of radius  $\delta$  that cover  $T$ ,  $B_1, \dots, B_{K(\delta)}$ . Make these balls disjoint by taking successive “set-minuses” and then we have a partition of  $T$ . Then

$$\limsup \mathbb{P}^* \left( \max_i \sup_{s,t \in T_i} |X_n(s) - X_n(t)| > \epsilon \right) \leq \limsup \mathbb{P}^* \left( \sup_{\rho(s,t) < \delta} |X_n(s) - X_n(t)| > \epsilon \right) < \eta$$

and we can apply the results of Theorem 2.6.

( $\Rightarrow$ ) If  $X_n$  is asymptotically tight, then  $g(X_n)$  is asymptotically tight for each continuous function  $g$ . Let  $K_1 \subset K_2 \subset \dots$  be compact sets with:

$$\liminf \mathbb{P}_*(X_n \in K_m^\epsilon) \geq 1 - 1/m.^5$$

For each  $m$  define a semimetric  $\rho_m$  on  $T$  by:

$$\rho_m(s, t) = \sup_{z \in K_m} |z(s) - z(t)|.$$

Then  $(T, \rho_m)$  is totally bounded. How? Cover  $K_m$  by finitely many balls of arbitrarily small radius  $\eta$  centered at  $z_1, \dots, z_k$ .<sup>6</sup> Partition  $\mathbb{R}^k$  into cubes of edge  $\eta$  and for every cube pick at most one  $t \in T$  such that  $(z_1(t), \dots, z_k(t))$  is in the cube. Since  $z_1, \dots, z_k$  are uniformly bounded,<sup>7</sup> this gives finitely many points  $t_1, \dots, t_p$ . Now, the balls  $\{t : \rho_m(t, t_i) < 3\eta\}$  cover  $T$ :  $t$  is in the ball around  $t_i$  for which  $(z_1(t), \dots, z_k(t))$  and  $(z_1(t_i), \dots, z_k(t_i))$  fall in the same cube. This in turn follows from the fact that  $\rho_m(t, t_i)$  can be bounded by  $2 \sup_{z \in K_m} \inf_i \|z - z_i\|_T + \sup_j |z_j(t_i) - z_j(t)|$ .<sup>8</sup>

Now set

$$\rho(s, t) = \sum_{m=1}^{\infty} 2^{-m} (\rho_m(s, t) \wedge 1).$$

<sup>5</sup>We can choose nested compact sets with this property because the union of a finite number of compact sets is compact and the probability functional is increasing with respect to the subset ordering.

<sup>6</sup>This is possible by compactness. Cover  $K_m$  by balls of radius  $\eta$  and then take a finite subcover.

<sup>7</sup>Recall that each  $z_i$  is in  $\ell^\infty(T)$  which is the space of all bounded functions from  $T \rightarrow \mathbb{R}$ . A finite collection of bounded functions is uniformly bounded

<sup>8</sup>Recall that  $\|f\|_T = \sup_{t \in T} |f(t)|$ ,  $\rho_m(t, t_i) = \sup_{z \in K_m} |z(t) - z(t_i)|$ ,  $z_1, \dots, z_k$  are the points (bounded functions of  $T$ ) around which balls of radius  $\eta$  cover  $K_m$ , and  $t_1, \dots, t_p$  are points of  $T$  such that the vector valued function  $(z_1(\cdot), \dots, z_k(\cdot))$  takes values only in cubes of edge length  $\eta$  of which one of  $t_1, \dots, t_p$  is an element. Then, applying the triangle inequality and the above statements:

$$\begin{aligned} \rho_m(t, t_i) &= \sup_{z \in K_m} |z(t) - z(t_i)| \\ &\leq \sup_{z \in K_m} |z(t) - z_j(t_i)| + |z_j(t_i) - z(t_i)| \\ &\leq \sup_{z \in K_m} |z(t) - z_j(t_i)| + |z_j(t_i) - z_j(t)| + |z_j(t) - z(t)| \\ &\leq 2 \sup_{z \in K_m} \|z - z_j\|_T + |z_j(t_i) - z_j(t)| \end{aligned}$$

Since this holds for all  $j$ , we obtain

$$\rho_m(t, t_i) \leq 2 \sup_{z \in K_m} \inf_j \|z - z_j\|_T + \sup_j |z_j(t) - z_j(t_i)|.$$

For any  $t$  such that  $(z_1(t), \dots, z_k(t))$  falls in the same cube as  $(z_1(t_i), \dots, z_k(t_i))$ , the first quantity is (strictly) bounded by  $2\eta$  by the definition of  $z_1, \dots, z_k$  whereas the second quantity is bounded by  $\eta$  because  $t$  falls in the same cube as  $t_i$ . Now, since, for each  $t \in T$ ,  $(z_1(t), \dots, z_k(t)) \in T$  must fall in the same cube as  $(z_1(t_i), \dots, z_k(t_i))$  for some  $i \in \{1, \dots, p\}$  we have that  $t \in \{\tilde{t} : \rho_m(t_i, \tilde{t}) < 3\eta\}$  for some  $i \in \{1, \dots, p\}$ . Since  $\eta$  is arbitrary, this shows that  $(T, \rho_m)$  is totally bounded.

Fix some  $\eta > 0$ . Take a natural number  $m$  with  $2^{-m} < \eta$ . Cover  $T$  with finitely many  $\rho_m$ -balls of radius  $m$ .<sup>9</sup> Let  $t_1, \dots, t_p$  be their centers, Since  $\rho_1 \leq \rho_2 \leq \dots$ ,<sup>10</sup> there is for every  $t$  a  $t_i$  with

$$\rho(t, t_i) \leq \sum_{k=1}^m 2^{-k} \rho_k(t, t_i) + 2^{-m} < 2\eta.$$
<sup>11</sup>

So  $(T, \rho)$  is totally bounded as well. It is clear from definitions that  $|z(s) - z(t)| \leq \rho_m(s, t)$  for every  $z \in K_m$  and that  $(\rho_m(s, t) \wedge 1) \leq 2^m \rho(s, t)$ .<sup>12</sup> Further, if  $\|z_0 - z\|_T < \epsilon$  for  $z \in K_m$ , then  $|z_0(s) - z_0(t)| < 2\epsilon + |z(s) - z(t)|$  for any pair  $s, t$ .<sup>13</sup> This gives us that

$$K_m^\epsilon \subset \left\{ z : \sup_{\rho(s, t) < 2^{-m}\epsilon} |z(s) - z(t)| \leq 3\epsilon \right\}.$$

The system of implications to get this is: if  $z \in K_m$  and  $\epsilon < 1$  then  $\rho(s, t) < 2^{-m}\epsilon \implies \rho_m(s, t) \leq \epsilon \implies |z(s) - z(t)| \leq \epsilon$ . That this holds for all  $z \in K_m$  gives that for  $z \in K_m^\epsilon$ ,  $\rho(s, t) < 2^{-m}\epsilon \implies |z(s) - z(t)| \leq 3\epsilon$ . Taking  $\epsilon \leq 1$  is without loss of generality. To finish not that this gives us that, for given  $\epsilon$  and  $m$  and for  $\delta < 2^{-m}\epsilon$

$$\liminf \mathbb{P}_* \left( \sup_{\rho(s, t) < \delta} |X_n(s) - X_n(t)| < 3\epsilon \right) \geq 1 - \frac{1}{m}.$$

This shows the backwards direction of Theorem 2.6 as well. As a note, this whole argument can be used with nets instead of sequences.  $\square$

**Remark.** Important not to forget the totally bounded part of the theorem. For example, in the example of the empirical CDF case, we need to show that  $\mathbb{R}$  is totally bounded. The good news is we have choice of semi-metric.

**Remark** (Connection to Arzela-Ascoli). Arzela-Ascoli: Let  $T$  be a set with metric  $\rho$  that is compact. Let  $C(T)$  be the set of all real valued continuous functions on  $T$ . Then  $A \subset C(T)$  is compact under  $|\cdot|_\infty$  if and only if it is equicontinuous and bounded.

We can think of Theorem 2.7 as a stochastic version of this. That is for

$$\liminf \mathbb{P}_* \left( \sup_{\rho(s, t) < \delta} |X_n(s) - X_n(t)| \leq \epsilon \right) \geq 1 - \eta.$$

The set of functions satisfying this condition is equicontinuous. So then, if  $X_n$  falls here it is in a compact set by Arzela-Ascoli (Theorem 1.3). Showing this is a focus later.

### 3 Empirical Processes

These notes follow Section 2 in VdV&W. So far, we have discussed theory for  $X_n \xrightarrow{L} X$  where both  $X_n$  and  $X$  are random elements in  $\ell^\infty(T)$ . The classic example that we have kept in mind is convergence of the empirical CDF process,  $X_n(t) = \frac{1}{\sqrt{n}} \sum_{i=1}^n (\mathbf{1}\{X_i \leq t\} - \mathbb{P}(X \leq t))$ . In this next section we will build on the theory developed to show the convergence of some empirical processes on  $\ell^\infty$ .

<sup>9</sup>This is possible because  $(T, \rho_m)$  is totally bounded by the above argument

<sup>10</sup>Because  $K_1 \subseteq K_2 \subseteq K_3 \dots$

<sup>11</sup>If  $t$  is distance at most  $\eta$  from  $t_i$  under  $\rho_m$ , it is also distance at most  $\eta$  from  $t_i$  under  $\rho_k$  for  $k \leq m$

<sup>12</sup>In the definition of  $\rho$  multiply left side and right side by  $2^m$ . A semimetric is always (weakly) positive.

<sup>13</sup>Same triangle inequality decomposition as above:

$$\begin{aligned} |z_0(s) - z_0(t)| &\leq |z_0(s) - z(s)| + |z(s) - z_0(t)| \\ &\leq |z_0(s) - z(s)| + |z(s) - z(t)| + |z(t) - z_0(t)| \\ &\leq 2\|z_0 - z\|_T + |z(s) - z(t)| \end{aligned}$$

**Definition 3.1** (Empirical Measure). For a random sample  $\{X_i\}_{i=1}^n$ , the empirical measure  $\mathbb{P}_n$  is the measure constructed from the sample (putting mass  $1/n$  at each  $X_i$ ). That is, for any set  $C$ :

$$\mathbb{P}_n(C) := \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \in C\}.$$

We can also write this in terms of the degenerate measures on each  $X_i$ :

$$\mathbb{P}_n := \frac{1}{n} \sum_{i=1}^n \delta_{X_i}.$$

**Definition 3.2** (Empirical Process). For a random sample  $\{X_i\}_{i=1}^n$  drawn from common distribution  $P$ , the empirical process  $\mathbb{G}_n$  is the scaled and demeaned measure on  $X$  given by:

$$\mathbb{G}_n(C) := \frac{1}{\sqrt{n}} \sum_{i=1}^n (\mathbb{1}\{X_i \in C\} - P(X_i \in C)).$$

This is often related to the empirical measure in Definition 3.1 by

$$\mathbb{G}_n = \sqrt{n} (\mathbb{P}_n - P).$$

Or written in terms of the degenerate measures on each  $X_i$ :

$$\mathbb{G}_n = \frac{1}{\sqrt{n}} \sum_{i=1}^n (\delta_{X_i} - P).$$

**Remark** (Notation). We will make the following notations to save space later on. For a measure  $\mathbb{Q}$  on a space let  $\mathbb{Q}f = \mathbb{E}_{\mathbb{Q}}[f(X)]$ . E.j:  $\mathbb{P}_n f = \mathbb{E}_n[f(X)] = \frac{1}{n} \sum_{i=1}^n f(X_i)$  and  $\mathbb{G}_n f = \frac{1}{\sqrt{n}} \sum_{i=1}^n (f(X_i) - Pf)$ .

With this notation:

$$\begin{aligned} \mathbb{P}_n f \xrightarrow{\text{a.s.}} Pf \text{ is just saying } & \frac{1}{n} \sum_{i=1}^n f(X_i) \xrightarrow{\text{a.s.}} \mathbb{E}[f(X)] \\ \mathbb{G}_n f \xrightarrow{L} N(0, \sigma^2) \text{ is just saying } & \frac{1}{\sqrt{n}} \sum_{i=1}^n (f(X_i) - \mathbb{E}[f(X)]) \xrightarrow{L} N(0, \sigma^2) \end{aligned}$$

By LLN and CLT we have that for any function  $f$ ,  $\mathbb{P}_n f \rightarrow_{a.s.} Pf$  and  $\mathbb{G}_n f \xrightarrow{L} N(0, P(f - Pf)^2)$

**Example 3.1** (Classes of Functions). LLN and CLT establish the behavior of the empirical measure  $\mathbb{P}_n f$  and the empirical process  $\mathbb{G}_n f$  for a fixed function  $f$  (which could even be vector valued). However, we often want to study the behavior of the empirical measure of empirical process over a class of functions  $\mathcal{F}$ . In this case we can think of  $\mathbb{G}_n(\mathcal{F})$  or  $\mathbb{P}_n(\mathcal{F})$  as random maps onto  $\ell^\infty(\mathcal{F})$ . The marginal,  $\mathbb{G}_n f$  or  $\mathbb{P}_n f$ , is then the behavior of the empirical measure/process for a single function  $f \in \mathcal{F}$ .

Mapping this back to the empirical CDF example of before let  $\mathcal{F} = \{f_t : \mathbb{R} \rightarrow \mathbb{R} \mid f_t(x) = \mathbb{1}\{x \leq t\}, t \in T\}$ . Before, we considered convergence of the whole CDF through the map  $X_n : \Omega_n \rightarrow \ell^\infty(T)$  with the marginals  $X_n(t) = \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\}$ . With these new definitions/notations, we equivalently consider convergence of the entire CDF through the map  $\mathbb{P}_n(\mathcal{F}) : \Omega_n \rightarrow \ell^\infty(\mathcal{F})$  with marginals  $\mathbb{P}_n f_t = \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\}$ .

This sort of notation/generalizability is useful as we can consider the behavior of the empirical measure or empirical process over a larger class of functions. For example, if we wanted to study an entire semiparametric model we may consider the behavior of  $\mathbb{G}_n(\mathcal{F})$  where

$$\mathcal{F} = \{f(x; \theta) \text{ for some } \theta \in \Theta\}.$$

Or, if we wanted to consider convergence after imposing some shape restriction, we may take

$$\mathcal{F} = \{f : X \rightarrow \mathbb{R} \mid f \text{ is monotonic}\}.$$

**Remark** (Notation). Sometimes we use  $\rightsquigarrow$  to denote weak convergence/convergence in law instead of  $\xrightarrow{L}$ .

**Remark** (Definition of  $\ell^\infty$  Space). It is useful to review the  $\ell^\infty(T)$  space for an arbitrary index space  $T$ . Define:

$$\ell^\infty(T) = \left\{ f : T \rightarrow \mathbb{R} : \sup_{t \in T} |f(t)| < \infty \right\} \quad (3.1)$$

and equip this space with the sup-norm,  $\|f\|_T = \sup_{t \in T} |f(t)|$ . Note that, for any  $\mathcal{F}$ ,  $\mathbb{G}_n(\mathcal{F})$  can be viewed as a random map into  $\ell^\infty(\mathcal{F})$  for each  $n$ . Boundedness comes from the finiteness of the sample. We will sometimes make the notation  $\|\mathbb{Q}\|_{\mathcal{F}} = \sup_{f \in \mathcal{F}} |\mathbb{Q}f|$  for a given measure  $\mathbb{Q}$ .

Now make some important definitions and then talk about how they relate to what we want to show.

**Definition 3.3** (Glivenko-Cantelli Class). A class of functions,  $\mathcal{F}$ , for which

$$\|\mathbb{P}_n - P\|_{\mathcal{F}} \rightarrow_p 0 \quad (3.2)$$

is called a Glivenko-Cantelli class, or a  $P$ -Glivenko-Cantelli class to emphasize the dependence on the underlying measure  $P$  from which the sample is drawn.

**Definition 3.4** (Donsker Class). A class of functions,  $\mathcal{F}$ , for which

$$\mathbb{G}_n(\mathcal{F}) \xrightarrow{L} \mathbb{G}(\mathcal{F}) \quad (3.3)$$

where  $\mathbb{G}$  is a tight, Borel measurable element in  $\ell^\infty(\mathcal{F})$ , is called a Donsker class, or  $P$ -Donsker class to emphasize the dependence on the underlying measure  $P$  from which the sample is drawn.

A Donsker class is trivially Glivenko-Cantelli.

**Example 3.2** (Some Donsker Classes). Some examples of function classes:

1. If  $\mathcal{F}$  consists of a single function with finite variance then  $\mathcal{F}$  is Donsker by the Central Limit Theorem. That is  $\mathbb{G}_n \xrightarrow{L} \mathbb{G}$  where  $\mathbb{G}$  is a tight element on  $\ell^\infty(\mathcal{F}) = \ell^\infty(\{f\})$
2. The class of functions  $\mathcal{F} = \{f(x) = x'\beta : \beta \in \mathcal{B}\}$  is Donsker if  $\mathcal{B}$  is bounded.
3. The class of monotonic densities on  $[0, 1]$  is Donsker.
4. The class of square integrable functions is not Donsker (too large).

How do we know if  $\mathbb{G}_N \rightsquigarrow \mathbb{G}$  where  $\mathbb{G}$  is a tight, Borel measurable element on  $\ell^\infty(\mathcal{F})$ ? By Theorem 2.5 we know that  $X_n$  weakly converges if and only if  $X_n$  is asymptotically tight and the marginals  $(X_n(t_1), \dots, X_n(t_k))$  converge weakly to a limit for every finite subset. Moreover, by Lemma 2.2 asymptotic measurability of the process is equivalent to asymptotic measurability of the marginals. By the Central Limit Theorem, we typically have weak convergence and asymptotic measurability of the marginals, what remains is to show asymptotic tightness.

Theorem 2.7 characterizes asymptotic tightness in terms of  $\rho$ -equicontinuity. Much of the work in showing tightness will be to find some semimetric  $\rho$  on  $\mathcal{F}$  such that for any  $\epsilon, \eta > 0$  there is a  $\delta > 0$  such that

$$\limsup_{n \rightarrow \infty} \mathbb{P}^* \left( \sup_{\rho(f,g) < \delta} |\mathbb{G}_n(f) - \mathbb{G}_n(g)| > \epsilon \right) < \eta. \quad (3.4)$$

A typical approach will be to let  $\mathcal{F}_\delta = \{f, g \in \mathcal{F}, \rho(f, g) < \delta\}$ . If we can show that, for some  $M(\delta)$  that goes

to 0 as  $\delta \downarrow 0$

$$\begin{aligned} \mathbb{E} \left[ \|\mathbb{G}_n\|_{\mathcal{F}_\delta} \right] &= \mathbb{E} \left[ \sup_{\rho(f,g) < \delta} |\mathbb{G}_n(f) - \mathbb{G}_n(g)| \right] \\ &= \mathbb{E} \left[ \sup_{\rho(f,g) < \delta} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \{f(X_i) - \mathbb{E}[f(X_i)] - g(X_i) + \mathbb{E}[g(X_i)]\} \right| \right] \\ &\leq M(\delta) \end{aligned}$$

Then, we would get the result in (3.4) by Markov's inequality. This type of result, that  $\mathbb{E} \left[ \|\mathbb{G}_n\|_{\mathcal{F}_\delta} \right] \leq M(\delta)$  is called a maximal inequality and is immensely useful.

Obtaining such a maximal inequality/establishing asymptotic tightness is dependent on the space not being “too large” (loosely speaking). In the example above, the class  $\mathcal{F} = \{f(x) = x'\beta \mid \beta \in \mathcal{B}\}$  is Donsker so long as  $\mathcal{B}$  is bounded. To illustrate, see in the single dimensional case that

$$\sup_{b \in \mathcal{B}} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n x_i b - \mathbb{E}[xb] \right| = \sup_{b \in \mathcal{B}} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n x_i - \mathbb{E}[x] \right| |b|.$$

If we don't impose  $|b| \leq M$  then this will blow up to  $+\infty$  with probability 1, whereas if we do we have that this is  $O_p(1)$ . For more involved function classes, we want a way of measuring whether  $\mathcal{F}$  is large or not. This motivates the definitions of bracketing and covering numbers below.

**Definition 3.5** (Covering Number). The covering number,  $\mathcal{N}(\epsilon, \mathcal{F}, \|\cdot\|)$  of a class of functions  $\mathcal{F}$  is the smallest number of balls of radius  $\epsilon$  under  $\|\cdot\|$  needed to cover the set  $\mathcal{F}$ .

**Definition 3.6** (Bracketing Number). Given two functions,  $\ell$  and  $u$ , the bracket  $[\ell, u]$  is the set of all functions  $f$  with  $\ell(x) \leq f \leq u(x)$  for all  $x$ . An  $\epsilon$ -bracket is a bracket  $[\ell, u]$  with  $\|u - \ell\| < \epsilon$ . The bracketing number  $\mathcal{N}_{[]}(\epsilon, \mathcal{F}, \|\cdot\|)$  is the minimum number of  $\epsilon$ -brackets needed to cover  $\mathcal{F}$ .

**Example 3.3** (Covering Number). Let  $A = [0, 1]$  and  $\|\cdot\|$  be the standard Euclidean norm<sup>1</sup>.

1. If  $\epsilon \geq 1/2$ , then a ball centered at  $1/2$  covers the entire interval so  $\mathcal{N}(\epsilon, A, |\cdot|) = 1$ .
2. If  $\epsilon < 1/2$ , then we need  $\lceil \frac{1}{2\epsilon} \rceil$  balls to cover  $A$ .

Note that (i) in this example the covering number coincides with the bracketing number (ii) in general the balls needed to cover  $\mathcal{F}$  need not be centered at points in  $\mathcal{F}$  (iii) (in general) as  $\epsilon \downarrow 0$  we have that  $\mathcal{N}(\epsilon, \mathcal{F}, \|\cdot\|) \uparrow \infty$ .

**Example 3.4** (Bracketing Number). Suppose  $x$  takes values in  $[0, 1]$  and let  $\mathcal{F} = \{f(x) = x\beta, \text{ for } \beta \in [0, 1]\}$ . Then, if  $\beta_i < \beta_{i+1}$ ,  $[x\beta_i, x\beta_{i+1}]$  forms a bracket containing all functions  $f(x) = x\beta$  with  $\beta_i \leq \beta \leq \beta_{i+1}$ . Further note that

$$\|x\beta_i - x\beta_{i+1}\| = \sup_{x \in [0, 1]} |x| |\beta_i - \beta_{i+1}| = |\beta_i - \beta_{i+1}|.$$

For any  $\epsilon > 0$  break up  $[0, 1]$  into  $[0, \epsilon, 2\epsilon, \dots]$  and take  $\beta_i = (i-1)\epsilon$  to get brackets  $[x\beta_i, x\beta_{i+1}]$  of size  $\epsilon$ . We need  $\lceil 1/\epsilon \rceil$  of these brackets to cover  $\mathcal{F}$  so that  $\mathcal{N}_{[]}(\epsilon, \mathcal{F}, \|\cdot\|_\infty) \leq \lceil 1/\epsilon \rceil < 2/\epsilon$ .

**Remark** (Bracketing vs. Covering Numbers). In general we have that  $\mathcal{N}(\epsilon, \mathcal{F}, \|\cdot\|) \leq \mathcal{N}_{[]}(\epsilon, \mathcal{F}, \|\cdot\|)$ , but no opposite relationship. This shows that bracketing numbers are in general stronger than covering numbers and give you better control over the class of functions.

We will see conditions for Glivenko-Cantelli and Donsker properties under both, but in general proving Glivenko-Cantelli involves using bracketing numbers whereas proving Donsker involves using covering numbers.

<sup>1</sup>If we want to view this as a function class we can equivalently say  $A$  is the set of constant functions taking values in the interval  $[0, 1]$  and consider any  $L_p$  norm on this class

In general, finding the covering/bracketing number will be difficult but we will learn some tips. Verifying that a set is Donsker will often come down to showing that the covering/bracketing number does not go to infinity “too fast.”

### 3.1 Maximal Inequalities for Finite Classes

For an arbitrary set of functions,  $\mathcal{F}$ , want to develop an inequality that looks something like:

$$\mathbb{E} \left[ \sup_{f \in \mathcal{F}} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n (f(x_i) - \mathbb{E}[f(x)]) \right| \right] \leq \text{size}(\mathcal{F}).$$

Or, rewriting in the notation of above:

$$\mathbb{E} \left[ \sup_{f \in \mathcal{F}} |\mathbb{G}_n f| \right] \leq \text{size}(\mathcal{F}).$$

This sort of inequality is useful as it can be used to show the uniform law of large numbers:

$$\mathbb{E} \left[ \sup_{f \in \mathcal{F}} |(\mathbb{P}_n - P) f| \right] \leq \frac{1}{\sqrt{n}} \text{size}(\mathcal{F}) + \text{Markov's Inequality}.$$

Or show asymptotic tightness through stochastic equicontinuity:

$$\mathbb{E} \left[ \sup_{\rho(f,g) < \delta} |\mathbb{G}_n(f - g)| \right] \leq \text{size}(\mathcal{F}_\delta) + \text{Theorem 2.7}.$$

However, often we may need to change the exact application of these maximal inequalities. We will work out where these come from as we go along. The inequality will be presented for general stochastic processes (for our purposes, a stochastic process is a random map into  $\ell^\infty(T)$ ). To build the maximal inequality, we will need to define a new norm which generalizes the  $L_p$  norms. We do so quickly below.

#### 3.1.1 Orlicz Norm

**Definition 3.7** (Orlicz Norm). Let  $\psi$  be a non-decreasing, convex function with  $\psi(0) = 0$  and  $X$  a random variable. Then, the Orlicz norm  $\|X\|_\psi$  is defined as

$$\|X\|_\psi = \inf \left\{ C > 0 : \mathbb{E} \psi \left( \frac{|X|}{C} \right) \leq 1 \right\} \quad (3.5)$$

Where here the infimum over the empty set is taken to be  $+\infty$ .

**Remark** (Orlicz norms generalize  $L_p$ ). Note that for any  $p \geq 1$  the function  $f(x) = x^p$  is convex and non-decreasing. With this in mind we can view the Orlicz norms as a generalization of the  $L_p$  norms to general convex and non-decreasing functions.

**Remark** (Orlicz p-norms). Of particular interest will be the Orlicz norms generated by the functions

$$\psi_p = e^{x^p} - 1.$$

for  $p \geq 1$ . The Orlicz norm in this case is often denoted  $\|\cdot\|_{\psi_p}$ . These norms give more weight to the tails of  $X$  than the standard  $L_p$  norms. It is not the case that these norms are uniformly larger than all  $L_p$  norms, however, we do have the inequalities

$$\begin{aligned} \|X\|_{\psi_p} &\leq \|X\|_{\psi_q} (\log 2)^{p/q} \\ \|X\|_p &\leq p! \|X\|_{\psi_1} \end{aligned}$$

**Remark** (Orlicz Norms and Markov's Inequality). Any Orlicz norm can be used to bound tail probabilities. Using Markov's inequality:

$$\mathbb{P}(|X| > x) \leq \mathbb{P}\left(\psi\left(|X|/\|X\|_\psi\right) \geq \psi\left(x/\|X\|_\psi\right)\right) \leq \frac{1}{\psi\left(x/\|X\|_\psi\right)}.$$

For  $\psi_p(x) = e^{x^p} - 1$  this leads to tail estimates like  $\exp(-Cx^p)$  for any random variable with a finite  $\psi_p$ -norm. Conversely, an exponential tail bound of this type shows that  $\|X\|_{\psi_p}$  is finite.

**Lemma 3.1** (Lemma 2.2.1 VdV&W). *Let  $X$  be a random variable with  $\mathbb{P}(|X| > x) \leq Ke^{-Dx^p}$  for every  $x$  and some (fixed) constants  $K$  and  $D$  and for some  $p \geq 1$ . Then, the Orlicz norm of  $X$  satisfies*

$$\|X\|_{\psi_p} \leq ((1+K)/D)^{1/p}$$

In particular, this will mean that for  $C = ((1+K)/D)^{1/p}$

$$\mathbb{E}\left[\psi\left(\frac{|X|}{C}\right)\right] \leq 1.$$

*Proof.* By Fundamental Theorem of Calculus and Tonelli's Theorem, for any constant  $B$ :

$$\mathbb{E}\left[e^{B|X|^p} - 1\right] = \mathbb{E}\int_0^{|X|^p} Be^{Bs} ds = \int_0^\infty \mathbb{P}\left(|X| > s^{1/p}\right) Be^{Bs} ds$$

Now use the inequality on the tails of  $|X|$ , plug in  $B = C^{-p} = D/(1+K)$ , and see that the final equality is bounded by 1.  $\square$

Using the fact that  $\max |X_i|^p \leq \sum |X_i|^p$  we obtain for the  $L_p$  norms, the result that

$$\left\|\max_{1 \leq i \leq m} X_i\right\|_p = \left(\mathbb{E} \max_{1 \leq i \leq m} |X_i|^p\right)^{1/p} \leq m^{1/p} \max_{1 \leq i \leq m} \|X_i\|_p.$$

We can generalize this for the Orlicz norm.

**Lemma 3.2** (Lemma 2.2.2 VdV&W). *Let  $\psi$  be a convex, non-decreasing, nonzero function with  $\psi(0) = 0$  and  $\limsup_{x,y \rightarrow \infty} \psi(x)\psi(y)/\psi(cxy) < \infty$  for some constant  $c$ . Then, for any random variables  $X_1, \dots, X_m$ ,*

$$\left\|\max_{1 \leq i \leq m} X_i\right\|_\psi \leq K\psi^{-1}(m) \max_{1 \leq i \leq m} \|X_i\|_\psi \quad (3.6)$$

For a constant  $K$  depending only on  $\psi$ .

*Proof.* Without loss of generality, assume that  $\psi(x)\psi(y) \leq \psi(cxy)$  for all  $x, y \geq 1$  and that  $\psi(1) \leq 1/2$ .<sup>1</sup> In this case,  $\psi(x/y) \leq \psi(cx)/\psi(y)$  for all  $x \geq y \geq 1$ .<sup>2</sup> Thus, for  $y \geq 1$  and any  $D$ :

$$\begin{aligned} \max_{1 \leq i \leq m} \psi\left(\frac{|X_i|}{Dy}\right) &\leq \max_{1 \leq i \leq m} \left[ \frac{\psi(c|X_i|/D)}{\psi(y)} + \psi\left(\frac{|X_i|}{Dy}\right) \mathbf{1}\left\{\frac{|X_i|}{Dy} < 1\right\} \right] \\ &\leq \sum_{i=1}^m \frac{\psi(c|X_i|/D)}{\psi(y)} + \psi(1) \end{aligned}$$

<sup>1</sup>If this is not the case there are constants  $\sigma \leq 1$  and  $\tau > 0$  such that  $\phi(x) = \sigma\psi(\tau x)$  satisfies these conditions. Apply the inequality to  $\phi$  and note that

$$\|X\|_\psi \leq \|X\|_\phi/(\sigma\tau) \leq \|X\|_\psi/\sigma.$$

<sup>2</sup> $x/y \geq 1$  so  $\psi(x/y)\psi(y) \leq \psi(cx/y)$

Let  $D = c \max_{1 \leq i \leq m} \|X_i\|_\psi$ , and take expectations to get:

$$\mathbb{E} \psi \left( \frac{\max_{1 \leq i \leq m} |X_i|}{Dy} \right) \leq \frac{m}{\psi(y)} + \psi(1).$$

When  $\psi(1) \leq 1/2$  take  $y = \psi^{-1}(2m)$ . Then:

$$\left\| \max_{1 \leq i \leq m} |X_i| \right\|_\psi \leq \psi^{-1}(2m) c \max_{1 \leq i \leq m} \|X_i\|_\psi.$$

By the convexity of  $\psi$  and the fact that  $\psi(0) = 0$ , it follows that  $\psi^{-1}(2m) \leq 2\psi^{-1}(m)$ . This gives the result.  $\square$

To review, we have established the following inequalities above:

1. For maximums of a finite number of random variables

$$\mathbb{E} \left[ \max_{1 \leq i \leq m} |X_i| \right] \leq m \max_{1 \leq i \leq m} \mathbb{E} [|X_i|].$$

2. Then, generalized this to the  $L_p$  norms

$$\left\| \max_{1 \leq i \leq m} |X_i| \right\|_{L_p} \leq m^{1/p} \max_{1 \leq i \leq m} \|X_i\|_{L_p}.$$

3. Then, generalized this using the Orlicz norm (Definition 3.7)

$$\left\| \max_{1 \leq i \leq m} |X_i| \right\|_\psi \leq K \psi^{-1}(m) \max_{1 \leq i \leq m} \|X_i\|_\psi.$$

In particular, taking  $\psi(a) = e^{a^2} - 1$ , we have that  $\mathbb{E} [\max_{1 \leq i \leq m} |X_i|] \leq C \sqrt{\log(m+1)}$  for any  $C$  such that  $\max_{1 \leq i \leq m} \mathbb{E} \left[ \psi \left( \frac{|X_i|}{C} \right) \right] \leq 1$ . Lemma 3.1 gives a condition for the existence of such a  $C$ .

### 3.2 Chaining and Inequalities for Infinite Classes

So far, we have developed inequalities that deal with finite number of random variables. These inequalities are useful for showing Donsker/Glivenko-Cantelli property for finite classes of functions,  $|\mathcal{F}| < \infty$ , just set  $X_i = \mathbb{G}_n f_i$ . However, we often want to show uniform convergence for (uncountably) infinite classes of sets,  $|\mathcal{F}| = |\mathbb{Q}|$  or  $|\mathcal{F}| = |\mathbb{R}|$ . To do this, we will use a technique called *chaining*.

Roughly speaking, this will work whenever our class of functions  $\mathcal{F}$  is “separable”, with respect to the empirical process  $\mathbb{G}_n$  (or empirical measure  $\mathbb{P}_n$ ). This means there is a countable subset  $\tilde{\mathcal{F}}$  of  $\mathcal{F}$  such that  $\sup_{\mathcal{F}} |\mathbb{G}_n(f)| = \sup_{\tilde{\mathcal{F}}} |\mathbb{G}_n(f)|$ . What does this buy us? If  $\tilde{\mathcal{F}}_0 \subset \tilde{\mathcal{F}}_1 \subset \tilde{\mathcal{F}}_2 \cdots \subset \tilde{\mathcal{F}}$  is an infinite sequence of sets whose union is  $\tilde{\mathcal{F}}$  and where each  $\tilde{\mathcal{F}}_i$  is finite, then:

$$\lim_{k \rightarrow \infty} \sup_{\tilde{\mathcal{F}}_k} |\mathbb{G}_n(f)| \stackrel{a.s.}{=} \sup_{\tilde{\mathcal{F}}} |\mathbb{G}_n(f)| \stackrel{\text{monotone convergence}}{\implies} \lim_{k \rightarrow \infty} \mathbb{E} \left[ \sup_{\tilde{\mathcal{F}}_k} |\mathbb{G}_n(f)| \right] = \mathbb{E} \left[ \sup_{\tilde{\mathcal{F}}} |\mathbb{G}_n(f)| \right].$$

and by separability, the last expectation is equal to the expectation of the supremum over the whole class  $\mathcal{F}$ . To make this work, we want to make sure that we can apply the inequalities that we developed in the past section. Specifically, we want to make sure that the conditions of Lemma 3.1 hold. To do so, make a definition.

**Definition 3.8** (Subgaussian Process). Let  $\mathbb{G}$  be a stochastic process on a space  $\mathcal{F}$  equipped with a metric  $d(\cdot, \cdot)$ . Then  $\mathbb{G}$  is subgaussian if

$$\mathbb{P}\left(|\mathbb{G}(f) - \mathbb{G}(g)| > x\right) \leq 2e^{-1/2x^2/d^2(f,g)} \quad (3.7)$$

for all  $f, g \in \mathcal{F}$  and any  $x \geq 0$ .

Also define a separable function as an analytic concept and then extend this to the case of stochastic processes.

**Definition 3.9** (Separable Function). A function  $f : A \rightarrow B$  from a topological space  $A$  into a topological space  $B$  is separable if there is a countable, dense, subset  $S \subset A$  such that for any closed  $F \subset B$  and any open  $I \subset A$ , if  $f(t) \in F$  for all  $t \in F \cap S$  then  $f(t) \in F$  for all  $t \in I$ . This is often denoted as an  $S$ -separable function to emphasize the dependence on the countable, dense subset  $S$ .

**Lemma 3.3** (Continuity and Separability). *A continuous function  $f : \mathcal{X} \rightarrow \mathcal{Y}$  from a separable space  $\mathcal{X}$  onto  $\mathcal{Y}$  is separable.*

**Definition 3.10** (Separable Process; Shalizi 2007). A stochastic process on a topological space  $\mathcal{F}$ ,  $\mathbb{G}(\cdot, \omega) : \Omega \rightarrow \ell^\infty(\mathcal{F})$ , is separable if there is a countable, dense, subset of  $\mathcal{F}$ ,  $\tilde{\mathcal{F}}$ , and a measure zero set  $N$  such that for all  $\omega \notin N$ ,  $\mathbb{G}(\cdot, \omega)$  is  $\tilde{\mathcal{F}}$ -separable.<sup>1</sup>

Separability can be roughly interpreted as ensuring that the behavior of the function (and therefore the stochastic process) can be well described by its behavior on countable subset. This ensures some of the properties that we've seen above, namely that  $\sup_{f \in \tilde{\mathcal{F}}} |\mathbb{G}(f)| \stackrel{a.s.}{=} \sup_{f \in \mathcal{F}} |\mathbb{G}(f)|$ . We are now ready for the main theorem of this subsection, the proof of which will rely on the chaining argument roughly discussed above.

**Theorem 3.1** (Theorem 2.2.4 VdV&W). *Let  $\mathbb{G}$  be a separable subgaussian process on a space  $\mathcal{F}$  equipped with a metric  $d(\cdot, \cdot)$  and let  $\text{diam}(\mathcal{F}) = \sup_{f,g \in \mathcal{F}} d(f, g)$ . Then*

$$\mathbb{E} \sup_{f,g \in \mathcal{F}} |\mathbb{G}(f) - \mathbb{G}(g)| \leq K \int_0^{\text{diam}(\mathcal{F})} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}, d)} d\epsilon \quad (3.8)$$

$$\mathbb{E} \sup_{f \in \mathcal{F}} |\mathbb{G}(f)| \leq \mathbb{E} |\mathbb{G}(f_0)| + K \int_0^{\text{diam}(\mathcal{F})} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}, d)} d\epsilon, \quad \forall f_0 \in \mathcal{F} \quad (3.9)$$

*Proof.* Proof proceeds in steps. Let  $M = \text{diam}(\mathcal{F}) = \sup_{f,g \in \mathcal{F}} d(f, g)$ . For any  $f_0, f \in \mathcal{F}$  we have that  $d(f_0, g) \leq M$ . First step will be to build a “chain” to almost any point in  $\mathcal{F}$ . Further, let  $\tilde{\mathcal{F}}$  be the dense subset as described in Definitions 3.9 and 3.10.

*Step 1: Building a Chain.* Pick any  $f_0 \in \tilde{\mathcal{F}}$  and let  $\tilde{\mathcal{F}}_0 = \{f_0\}$ . Build nesting sets,  $\mathcal{F}_0 \subset \tilde{\mathcal{F}}_1 \subset \tilde{\mathcal{F}}_2 \subset \dots \subset \tilde{\mathcal{F}}$ , such that for each  $k \in \mathbb{N}$   $\tilde{\mathcal{F}}_k = \{f_1, \dots, f_{m(k)}\}$  is a maximal collection of points such that  $d(f_k, g_k) > \frac{M}{2^k}$  for any  $f_k, g_k \in \mathcal{F}_k$ . By definition of the packing numbers we know that  $\mathcal{N}\left(\frac{M}{2^{k+1}}, \mathcal{F}, d\right)$  balls cover  $\mathcal{F}$ . Putting a point at the center of each of these balls creates points that are at least distance  $\frac{M}{2^k}$  from each other. Similarly, if we could fit more points at least distance  $\frac{M}{2^k}$  distance away from each other than we could pack more balls of radius  $\frac{M}{2^{k+1}}$  into  $\mathcal{F}$  by centering a ball at each point. So,  $|\tilde{\mathcal{F}}_k| \leq \mathcal{N}\left(\frac{M}{2^{k+1}}, \mathcal{F}, d\right)$  (Inequality comes because each  $\tilde{\mathcal{F}}_k$  has to contain all previous sets).

Finally, link each point  $f_k \in \tilde{\mathcal{F}}_k$  to a unique point  $f_{k-1} \in \tilde{\mathcal{F}}_{k-1}$  such that  $d(f_k, f_{k-1}) \leq \frac{M}{2^{k-1}}$ .<sup>2</sup>

<sup>1</sup>Note that this requires a topology on  $\mathcal{F}$ . In the applications we will be talking about  $\mathcal{F}$  will be equipped with a metric  $d$ . This will generate a topology.

<sup>2</sup>I found it helpful to remember here that  $\tilde{\mathcal{F}}_{k-1} \subset \tilde{\mathcal{F}}_k$ . If no such  $f_{k-1}$  exists we could add  $f_k$  to  $\tilde{\mathcal{F}}_{k-1}$ , a contradiction. If  $f_k \in \tilde{\mathcal{F}}_{k-1}$  we can link it to itself.

*Step 2: Use the chain to build a bound.* Using these links, for any  $f_k, g_k \in \tilde{\mathcal{F}}_k$  we can build a chain back to  $f_0$ :

$$\begin{aligned} |\mathbb{G}(f_k) - \mathbb{G}(g_k)| &= \left| (\mathbb{G}(f_k) - \mathbb{G}(f_0)) - (\mathbb{G}(g_k) - \mathbb{G}(f_0)) \right| \\ &= \left| \sum_{j=0}^k (\mathbb{G}(f_j) - \mathbb{G}(f_{j-1})) - \sum_{j=0}^k (\mathbb{G}(g_j) - \mathbb{G}(g_{j-1})) \right| \end{aligned}$$

By the triangle inequality:

$$\mathbb{E} \left[ \max_{g_k, f_k \in \tilde{\mathcal{F}}_k} |\mathbb{G}(f_k) - \mathbb{G}(g_k)| \right] \leq 2 \sum_{j=0}^K \mathbb{E} \left[ \max_{s_i \in \tilde{\mathcal{F}}_i} |\mathbb{G}(s_i) - \mathbb{G}(s_{i-1})| \right] \quad (\text{P-1})$$

With this setup, we can use the maximal inequalities developed above, applying them to the finite sets  $\tilde{\mathcal{F}}_k$ .

*Step 3: Try to control the jumps.* Recall that there are at most  $\mathcal{N}\left(\frac{M}{2^{j+1}}, \mathcal{F}, d\right)$  points in  $\mathcal{F}_k$  and that  $d(s_k, s_{k-1}) \leq \frac{M}{2^{k-1}}$ . By our maximal inequality in Lemma 3.2, taking  $\psi(a) = e^{a^2} - 1$  we have that

$$\mathbb{E} \left[ \max_{s_j \in \tilde{\mathcal{F}}_j} |\mathbb{G}(s_j) - \mathbb{G}(s_{j-1})| \right] \leq C_j \sqrt{\log \left( \mathcal{N}\left(\frac{M}{2^{j+1}}, \mathcal{F}, d\right) + 1 \right)}.$$

For any constant  $C_j$  such that

$$\mathbb{E} \left[ \exp \left( \frac{(\mathbb{G}(s_j) - \mathbb{G}(s_{j-1}))^2}{c_j^2} \right) - 1 \right] \leq 1, \quad \forall s_j \in \tilde{\mathcal{F}}_j.$$

Since  $\mathbb{G}$  is subgaussian we know that  $\mathbb{P}\left(|\mathbb{G}(f) - \mathbb{G}(g)| > x\right) \leq 2e^{-\frac{1}{2}x^2/d^2(f,g)}$ . By construction, we know that  $d(s_j, s_{j-1}) \leq \frac{M}{2^{j-1}}, \forall s_j \in \tilde{\mathcal{F}}_j$ . So

$$\mathbb{P}\left(|\mathbb{G}(s_j) - \mathbb{G}(s_{j-1})| > x\right) \leq 2e^{-\frac{1}{2} \frac{x^2}{\lceil M/2^{j-1} \rceil^2}}.$$

By Lemma 3.1 we can take  $C_j = \frac{\sqrt{3}M}{2^{j-1}}$  and combine with the other results in this section to get

$$\mathbb{E} \left[ \max_{s_j \in \tilde{\mathcal{F}}_j} |\mathbb{G}(s_j) - \mathbb{G}(s_{j-1})| \right] \leq \frac{\sqrt{3}M}{2^{j-1}} \sqrt{\log \left( \mathcal{N}\left(\frac{M}{2^{j+1}}, \mathcal{F}, d\right) + 1 \right)} \quad (\text{P-2})$$

*Step 4: Combine Results of Previous Steps.* Combine the inequalities from (P-1) and (P-2) to get

$$\mathbb{E} \left[ \max_{g_k, f_k \in \tilde{\mathcal{F}}_k} |\mathbb{G}(f_g) - \mathbb{G}(g_k)| \right] \leq \sqrt{12}M \sum_{j=0}^k \frac{1}{2^{j-1}} \sqrt{\log \left( \mathcal{N}\left(\frac{M}{2^{j+1}}, \mathcal{F}, d\right) + 1 \right)}$$

With some complex rearranging of squares, we can bound the sum in the display by it's integral up to a constant scale, dropping the added 1 in the log in the process.<sup>3</sup> That is, we ultimately obtain for some constant  $K$ :

$$\mathbb{E} \left[ \max_{g_k, f_k \in \tilde{\mathcal{F}}_k} |\mathbb{G}(f_g) - \mathbb{G}(g_k)| \right] \leq K \int_0^M \sqrt{\log(\mathcal{N}(\epsilon, \mathcal{F}, d))} d\epsilon \quad (\text{P-3})$$

<sup>3</sup>Here we use the fact that  $\log(1+m) \leq 2\log(m)$  for  $m \geq 2$

*Step 5: Conclude by Separability.*  $\{\tilde{\mathcal{F}}_k\}_{k=1}^{\infty}$  is an increasing sequence of sets that approaches  $\tilde{\mathcal{F}}$  and note that the bound in (P-3) does not depend on (little)  $k$ . So, invoking monotone convergence and separability of  $\mathbb{G}$ :

$$\begin{aligned} \mathbb{E} \left[ \sup_{f,g \in \mathcal{F}} |\mathbb{G}(f) - \mathbb{G}(g)| \right] &= \mathbb{E} \left[ \sup_{f,g \in \tilde{\mathcal{F}}} |\mathbb{G}(f) - \mathbb{G}(g)| \right] \\ &= \lim_{k \rightarrow \infty} \mathbb{E} \left[ \max_{f,g \in \tilde{\mathcal{F}}} |\mathbb{G}(f) - \mathbb{G}(g)| \right] \\ &\leq K \int_0^M \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}, d)} d\epsilon \end{aligned}$$

This is the inequality in equation (3.8). To get equation (3.9) fix any  $f_0$  and apply triangle inequality.  $\square$

**Remark** (Comments on Theorem 3.1). Theorem 3.1 is an involved result. Some remarks below.

1. We have shown that if  $\mathbb{G}_n$  is a separable subgaussian process then

$$\mathbb{E} \left[ \sup_{f,g \in \mathcal{F}} |\mathbb{G}_n(f) - \mathbb{G}_n(g)| \right] \leq K \int_0^{\text{diam}(\mathcal{F})} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}, d)} d\epsilon.$$

Note that the right hand side does not depend on  $\mathbb{G}_n$  at all! Only on the “size” of  $\mathcal{F}$ .

2. So, suppose we want to show that  $\mathbb{G}_n$  is an asymptotically tight process on  $\mathcal{F}$ . By Theorem 2.7 it is sufficient (and necessary) to show that for every  $\epsilon, \eta > 0$  there is a  $\delta > 0$  such that:

$$\limsup_{n \rightarrow \infty} \mathbb{P} \left( \sup_{\rho(f,g) \leq \delta} |\mathbb{G}_n(f) - \mathbb{G}_n(g)| > \epsilon \right) < \eta.$$

Let  $\mathcal{F}_\delta = \{s = f - g : f, g \in \mathcal{F} \text{ and } \rho(f, g) \leq \delta\}$ . The above can be restated as showing that  $\exists \delta > 0$  such that:

$$\limsup_{n \rightarrow \infty} \mathbb{P} \left( \sup_{s \in \mathcal{F}_\delta} |\mathbb{G}_n(s)| > \epsilon \right) < \eta.$$

By Markov’s inequality we can bound the probability in the above display by

$$\frac{1}{\epsilon} \mathbb{E} \left[ \sup_{s \in \mathcal{F}_\delta} |\mathbb{G}_n(s)| \right] \leq \frac{K}{\epsilon} \int_0^\delta \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}, d)} d\epsilon$$

And then we can sent the RHS to 0 by sending  $\delta \downarrow 0$  as long as the integral on the RHS is finite. Asymptotic tightness plus convergence of marginals will give convergence to a tight element in  $\ell^\infty(\mathcal{F})$  by Theorem 2.5. What remains is to show the conditions on  $\mathbb{G}$ , separability and subgaussian.

### 3.3 Symmetrization

Symmetrization is a technique that will allow us to get/show(?) a subgaussian process. This follows the discussion in Chapter 2.2.1 and 2.3 in VanDerVaart and Wellner.

What sort of variables are subgaussian? A classic example below.

**Definition 3.11** (Rademacher Random Variable). Random variable  $\epsilon_i : \Omega_i \rightarrow \mathbb{R}$  is a Rademacher random variable if  $\mathbb{P}(\epsilon_i = 1) = \mathbb{P}(\epsilon_i = -1) = 1/2$ .

The following lemma shows that a particular process consisting of Rademacher random variables is subgaussian.

**Lemma 3.4** (Hoeffding's Inequality). *Let  $a_1, \dots, a_n$  be constants and  $\epsilon_1, \dots, \epsilon_n$  be independent Rademachar random variables. Then*

$$\mathbb{P}\left(\left|\sum_{i=1}^n a_i \epsilon_i\right| > x\right) \leq 2e^{-\frac{1}{2} \frac{x^2}{\|a\|^2}}.$$

where  $\|a\|$  denotes the Euclidean norm of  $a$ .

*Proof.* (From VdV&W, Lemma 2.2.7) For any  $\lambda$  and any Rademachar random variable  $\epsilon$  one has that  $\mathbb{E}e^{\lambda\epsilon} = (e^\lambda + e^{-\lambda})/2$ . By power series expansion:

$$\begin{aligned} e^\lambda &= 1 + \lambda + \frac{\lambda^2}{2!} + \frac{\lambda^3}{3!} + \dots \\ e^{-\lambda} &= 1 - \lambda + \frac{\lambda^2}{2!} - \frac{\lambda^3}{3!} + \dots \\ \Rightarrow (e^\lambda + e^{-\lambda})/2 &= 1 + \frac{\lambda^2}{2!} + \frac{\lambda^4}{4!} + \frac{\lambda^6}{6!} \dots \\ &\leq 1 + \frac{\lambda^2}{2} + \frac{\lambda^4}{2^2 \cdot 2!} + \frac{\lambda^6}{2^3 \cdot 3!} \\ &= e^{\lambda^2/2} \end{aligned}$$

where in the last inequality we use that  $2^k \cdot k! \leq (2k)!$  so that in total we have that  $\mathbb{E}e^{\lambda\epsilon} = (e^\lambda + e^{-\lambda})/2 \leq e^{\lambda^2/2}$ . Take  $\lambda = x/\|a\|^2$  and apply Markov's inequality to get the result.  $\square$

**Example.** For any functions  $f, g$  we have that

$$\mathbb{P}\left(\left|\sum_{i=1}^n \frac{\epsilon_i}{\sqrt{n}} (f(x_i) - g(x_i))\right| > x \mid \{X_i\}\right) \leq 2e^{-\frac{1}{2} \frac{x^2}{d_n^2(f,g)}}.$$

where  $d_n^2(f, g) := \frac{1}{n} \sum_{i=1}^n (f(x_i) - g(x_i))^2$  is the square of the prediction norm.

We would like to use the maximal inequality in Theorem 3.1 to control  $\mathbb{E}[\sup_{f,g} |\mathbb{G}_n(f) - \mathbb{G}_n(g)|]$ , but the problem is that  $\mathbb{G}_n$  is not (in general), subgaussian. However, from Lemma 3.4 we know that, at least conditional on our data,  $\mathbb{G}_n^\circ := \frac{1}{\sqrt{n}} \sum \epsilon_i (f(x_i) - g(x_i))$  is. Strategy will be to relate the two processes,  $\mathbb{G}_n$  and  $\mathbb{G}_n^\circ$ .

Before starting, it is useful to formally define the probability space that we are working with. Let  $\epsilon_1, \dots, \epsilon_n$  be i.i.d Rademachar random variables that are generated independent of  $(X_1, \dots, X_n)$ , our observed data. Define the symmetrized process:

$$\mathbb{P}_n^\circ f = \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i).$$

Because  $\mathbb{P}_n^\circ$  is subgaussian, conditional on  $X_1, \dots, X_n$ , it can be easier to study. We want to bound supremum of the process  $\mathbb{P}_n - P$  by that of the symmetrized process. To formalize these bounds, we have to be careful about the non-measurability of supremum like  $\|\mathbb{P}_n - P\|_{\mathcal{F}}$ .<sup>1</sup>

In the following discussion, outer expectations of functions of  $X_1, \dots, X_n$  are assumed to be taken with respect to the coordinate projection of the infinite product space  $(\mathcal{X}^\mathbb{N}, \mathcal{A}^\mathbb{N}, P^\mathbb{N})$  onto its first  $n$  coordinates,  $(\mathcal{X}^n, \mathcal{A}^n, P^n)$ .<sup>2</sup> When auxiliary variables, independent of the  $X$ 's are involved, as in the next lemma, we can use a similar convention. The underlying probability space is assumed to be of the form  $(\mathcal{X}^n, \mathcal{A}^n, P^n) \times$

<sup>1</sup>Even if  $\mathcal{F}$  is a class of measurable functions, the supremum may not be measurable.

<sup>2</sup>That is the outer expectation is taken relative to  $P^n$  where  $P^n$  is defined from the projection of the infinite product space onto its first  $n$  coordinates

$(\mathcal{Z}, \mathcal{C}, Q)$ . Independence is understood in terms of a product probability space.<sup>3</sup> To manage all this, we take advantage of a modified Fubini's theorem for outer expectations, stated here without proof.

**Lemma 3.5** (Fubini's Theorem, Lemma 1.2.6 VdV&W). *Let  $T$  be defined on a product probability space. Then*

$$\mathbb{E}_* T \leq \mathbb{E}_{1*} \mathbb{E}_{2*} T \leq \mathbb{E}_1^* \mathbb{E}_2^* T \leq \mathbb{E}^* T.$$

*Proof.* For the last inequality, we can assume that  $\mathbb{E}^* T < \infty$  so that  $\mathbb{E}^* T = \mathbb{E} T^*$ . Since  $T^*$  is jointly measurable with respect to the product  $\sigma$ -field, the map  $\omega_2 \mapsto T^*(\omega_1, \omega_2)$  is a measurable majorant of  $\omega_2 \mapsto T(\omega_1, \omega_2)$  for  $P_1$  almost all  $\omega_1$ . Hence  $\int T^*(\omega_1, \omega_2) dP_2(\omega_2) \geq (\mathbb{E}_2^* T)(\omega_1)$  for  $P_1$  almost all  $\omega_1$ . Further, by Fubini's theorem for standard integrals, this is a measurable function of  $\omega_1$ . Thus the integral of this with respect to  $P_1$  is an upper bound for  $\mathbb{E}_1^* \mathbb{E}_2^* T$ . Since  $T^*$  is jointly measurable, by another application Fubini's theorem for standard integrals:

$$\mathbb{E}^* T = \mathbb{E} T^* = \int \left( \int T^*(\omega_1, \omega_2) dP_2(\omega_2) \right) dP_1(\omega_1) \geq \mathbb{E}_1^* \mathbb{E}_2^* T.$$

The inequalities for inner expectations hold by considering  $-T$ . □

**Lemma 3.6** (Symmetrization). *For every non-decreasing, convex,  $\Phi : \mathbb{R} \rightarrow \mathbb{R}$  and class of measurable functions  $\mathcal{F}$ :*

$$\mathbb{E}^* \Phi (\|\mathbb{P}_n - P\|_{\mathcal{F}}) \leq \mathbb{E}^* \Phi (2 \|\mathbb{P}_n^\circ\|_{\mathcal{F}}).$$

*Where outer expectations are calculated as described above.*

*Proof.* Let  $Y_1, \dots, Y_n$  be independent copies of  $X_1, \dots, X_n$  (independently drawn from the same joint distribution as  $X_1, \dots, X_n$ , defined formally as the coordinate projections on the last  $n$  coordinates in the product space  $(\mathcal{X}^n, \mathcal{A}^n, P^n) \times (\mathcal{Z}, \mathcal{C}, Q) \times (\mathcal{X}^n, \mathcal{A}^n, P^n)$ ).

For fixed values  $X_1, \dots, X_n$  applying Jensen's inequality to the absolute value gives:

$$\|\mathbb{P}_n - P\|_{\mathcal{F}} = \sup_{f \in \mathcal{F}} \frac{1}{n} \left| \sum_{i=1}^n [f(X_i) - \mathbb{E} f(Y_i)] \right| \leq \mathbb{E}_Y^* \sup_{f \in \mathcal{F}} \frac{1}{n} \left| \sum_{i=1}^n [f(X_i) - f(Y_i)] \right|.$$

where  $\mathbb{E}_Y^*$  is the outer expectation with respect to  $Y_1, \dots, Y_n$  computed for  $P^n$ . Again applying Jensen's inequality gives:

$$\Phi (\|\mathbb{P}_n - P\|_{\mathcal{F}}) \leq \mathbb{E}_Y^* \Phi \left( \left\| \frac{1}{n} \sum_{i=1}^n [f(X_i) - f(Y_i)] \right\|_{\mathcal{F}}^{\star Y} \right).$$

where  $f^{\star Y}$  is the minimal measurable majorant of  $f$  with respect to the distribution of  $Y$ . Because  $\Phi$  is non-decreasing and continuous, the  $\star Y$  inside  $\Phi$  can be moved to  $\mathbb{E}_Y^*$ . In total then:

$$\Phi (\|\mathbb{P}_n - P\|_{\mathcal{F}}) \leq \mathbb{E}_Y^* \Phi \left( \left\| \frac{1}{n} \sum_{i=1}^n [f(X_i) - f(Y_i)] \right\|_{\mathcal{F}} \right).$$

Next, take the expectation with respect to  $X_1, \dots, X_n$  of the above quantity to get:

$$\mathbb{E}^* \Phi (\|\mathbb{P}_n - P\|_{\mathcal{F}}) \leq \mathbb{E}_X^* \mathbb{E}_Y^* \Phi \left( \left\| \frac{1}{n} \sum_{i=1}^n [f(X_i) - f(Y_i)] \right\|_{\mathcal{F}} \right).$$

---

<sup>3</sup>Two sub-sigma algebras,  $\mathcal{A}_1, \mathcal{A}_2 \subset \mathcal{A}$  are considered independent if  $\mathbb{P}(A_1 A_2) = \mathbb{P}(A_1) \mathbb{P}(A_2)$  for any  $A_1 \in \mathcal{A}_1, A_2 \in \mathcal{A}_2$ . The sigma algebra generated by a random map  $X : (\Omega, \mathcal{A}, \mathbb{P}) \rightarrow (\mathcal{X}, \mathcal{B})$  is the smallest sigma algebra on  $\Omega$  that makes  $X$  measurable,

$$\sigma(X) := \{X^{-1}(B) : B \in \mathcal{B}\}.$$

Two random variables,  $X, Y$ , defined on the same probability space are independent if their generated sigma algebras,  $\sigma(X), \sigma(Y)$ , are independent. In the context of having independent draws  $X_1, \dots, X_n$  we can think of this as the projection mappings  $\pi_i(\mathcal{X}^n)$  being independent.

Adding a minus sign in front of the term  $[f(X_i) - f(Y_i)]$  has the effect of exchanging  $X_i$  and  $Y_i$ . By construction of the underlying probability space this does not change the expectation. Hence, the expression

$$\mathbb{E}^* \Phi \left( \frac{1}{n} \left\| \sum_{i=1}^n e_i [f(X_i) - f(Y_i)] \right\| \right).$$

is the same for any  $n$ -tuple  $(e_1, \dots, e_n) \in \{-1, 1\}^n$ . So:

$$\mathbb{E}^* \Phi \left( \|\mathbb{P}_n - P\|_{\mathcal{F}} \right) \leq \mathbb{E}_{\epsilon} \mathbb{E}_{X,Y}^* \Phi \left( \left\| \sum_{i=1}^n \epsilon_i [f(X_i) - f(Y_i)] \right\|_{\mathcal{F}} \right).$$

where each  $\epsilon_i$  is an independent Rademacher random variable and  $\epsilon = (\epsilon_1, \dots, \epsilon_n)$ . By triangle inequality and convexity of the  $\Phi$ :

$$\begin{aligned} & \mathbb{E}_{\epsilon} \mathbb{E}_{X,Y}^* \Phi \left( \left\| \sum_{i=1}^n \epsilon_i [f(X_i) - f(Y_i)] \right\|_{\mathcal{F}} \right) \\ & \leq \mathbb{E}_{\epsilon} \mathbb{E}_{X,Y}^* \Phi \left( \left\| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right\|_{\mathcal{F}} + \left\| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(Y_i) \right\|_{\mathcal{F}} \right) \\ & \leq \frac{1}{2} \mathbb{E}_{\epsilon} \mathbb{E}_{X,Y}^* \Phi \left( 2 \left\| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right\|_{\mathcal{F}} \right) + \frac{1}{2} \mathbb{E}_{\epsilon} \mathbb{E}_{X,Y}^* \Phi \left( 2 \left\| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(Y_i) \right\|_{\mathcal{F}} \right) \\ & \leq \mathbb{E}^* \Phi \left( 2 \|\mathbb{P}_n^{\circ}\|_{\mathcal{F}} \right) \end{aligned}$$

where we use the fact that a repeated outer expectation can be bounded above by a joint outer expectation,  $\mathbb{E}_{\epsilon} \mathbb{E}_{X,Y}^* \leq \mathbb{E}_{\epsilon,X,Y}^* (= \mathbb{E}^*)$  using Lemma 3.5.  $\square$

**Corollary 3.1** (Symmetrization of Empirical Process, Andres' Notes). *For real valued processes as described above:*

$$\mathbb{E}^* \left[ \sup_{f \in \mathcal{F}} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n f(X_i) - P f(X_i) \right| \right] \leq 2 \mathbb{E}^* \left[ \sup_{f \in \mathcal{F}} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right].$$

*Proof.* Take  $\Phi(x) = |x|$ . All norms on  $\mathbb{R}$  are equivalent to  $|\cdot|$ . Lemma 3.6 then gives us that  $\mathbb{E}^* \|\mathbb{P}_n - P\|_{\mathcal{F}} \leq 2 \mathbb{E}^* \|\mathbb{P}_n^{\circ}\|_{\mathcal{F}}$ . Expand this out and scale by  $\sqrt{n}$  to get the result. For non real-valued processes (vector valued, function valued, etc.) we can replace  $|\cdot|$  with  $\|\cdot\|$  above.  $\square$

**Remark.** The proof of Corollary 3.1 uses the fact that Lemma 3.6 is not an asymptotic bound, it holds in every finite sample.

We now have the pieces to show a class of functions  $\mathcal{F}$  is either

- Glivenko-Cantelli, i.e that  $\|\mathbb{P}_n - P\|_{\mathcal{F}} = o_p(1)$ . We will do this by placing conditions on the bracketing/covering numbers.
- Donsker, i.e that  $\mathbb{G}_n(\mathcal{F}) \xrightarrow{L} \mathbb{G}(\mathcal{F})$  for some tight  $\mathbb{G}$ . To do so, we will use covering numbers. The system of arguments needed to show this is usually as follows:
  - By Theorem 2.5 weak convergence to a tight limit is equivalent to asymptotic tightness and weak convergence of the marginals.
  - Weak convergence of the marginals is generally provided by CLT. Theorem 2.7 shows that asymptotic tightness is equivalent to uniform  $\rho$ -equicontinuity (Definition 1.18)

- Asymptotic equicontinuity holds if  $\mathbb{E} \left[ \sup_{f \in \mathcal{F}_\delta} |\mathbb{G}_n(f)| \right]$  goes to 0 as  $\delta \downarrow 0$ . Theorem 3.1 gives conditions where this is possible for separable, subgaussian processes.
- Lemma 3.3 suggests separability if  $\mathcal{F}$  is separable. Lemma 3.4 gives us that the Rademachar process is subgaussian conditional on  $X_1, \dots, X_n$ . Combining with Theorem 3.1 gives

$$\mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_\delta} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] \leq \int_0^{\text{diam}(\mathcal{F}_\delta)} \sqrt{\log \mathcal{N}(s, \mathcal{F}_\delta, L_2(\mathbb{P}_n))} ds$$

where  $L_2(\mathbb{P}_n) = \frac{1}{n} \sum_{i=1}^n f(X_i)^2$  is the  $L_2$  norm with respect to the empirical measure. Since  $X$  is random this norm will also end up random. This seems like it will make dealing with

$$\mathbb{E} \left[ \int_0^{\text{diam}(\mathcal{F}_\delta)} \sqrt{\log \mathcal{N}(s, \mathcal{F}_\delta, L_2(\mathbb{P}_n))} ds \right]$$

painful, but we end up having good bounds for this.

- Lemma 3.6, and in particular Corollary 3.1, relates the empirical process to the Rademachar process. Take expectations with respect to  $X$  in the above bound to bound the and apply the symmetrization lemma to get bounds on the empirical process of interest.

We next move to verifying the various conditions and applying them to show that some specific processes are Glivenko-Cantelli or Donsker.

### 3.4 Glivenko-Cantelli

This subsection follows Section 2.4 in Van DerVaart and Wellner. Goal is to establish conditions for a uniform law of large numbers using bracketing and covering numbers.

**Theorem 3.2** (Theorem 2.4.1 VdV&W). *Let  $\mathcal{F}$  be a class of measurable functions such that*

$$\mathcal{N}_{[]}(\epsilon, \mathcal{F}, L_1(P)) < \infty$$

*for every  $\epsilon > 0$ . Then  $\mathcal{F}$  is Glivenko-Cantelli.*

*Proof.* Fix  $\epsilon > 0$ . Choose finitely many  $\epsilon$ -brackets  $[l_i, u_i]$  whose union contains  $\mathcal{F}$  and such that  $P(u_i - l_i) < \epsilon$  for every  $i$ . Then, for every  $f \in \mathcal{F}$  there is a bracket,  $l_i \leq f \leq u_i$ , such that:

$$\begin{aligned} (\mathbb{P}_n - P)f &\leq \mathbb{P}_n u_i - Pf \leq (\mathbb{P}_n - P)u_i + P(u_i - f) \leq (\mathbb{P}_n - P)u_i + \epsilon \\ (\mathbb{P}_n - P)f &\geq \mathbb{P}_n l_i - Pf \geq (\mathbb{P}_n - P)l_i + P(l_i - f) \geq (\mathbb{P}_n - P)l_i - \epsilon \end{aligned}$$

Consequently,

$$\begin{aligned} \sup_{f \in \mathcal{F}} (\mathbb{P}_n - P)f &\leq \max_i (\mathbb{P}_n - P)u_i + \epsilon \\ \inf_{f \in \mathcal{F}} (\mathbb{P}_n - P)f &\geq \min_i (\mathbb{P}_n - P)l_i - \epsilon \end{aligned}$$

By the strong law of large numbers, both the maximums and the minimums on the right hand side of the inequalities above converge almost surely to 0. Combination these yields that  $\limsup \|\mathbb{P}_n - P\|_{\mathcal{F}}^* \leq \epsilon$  almost surely for every  $\epsilon > 0$ . Take  $\epsilon \downarrow 0$  to see that the  $\limsup$  must be 0 almost surely.  $\square$

**Remark.** Some comments on Theorem 3.2:

1. Proof is really quite straightforward. Bracketing gives pointwise control so just use the upper and lower bounds.
2. No measurability condition is needed and no requirements on the rate of growth of  $\mathcal{N}_{[]}(\epsilon, \cdot, \cdot)$  as  $\epsilon \downarrow 0$ .

**Example** (Empirical CDF is Glivenko-Cantelli). Let  $X$  be a scalar random variable.<sup>1</sup> We want to show that

$$\sup_{t \in \mathbb{R}} \left| \frac{1}{n} \sum_{i=1}^n \mathbb{1}\{X_i \leq t\} - P(X_i \leq t) \right| = o_p(1).$$

Let  $\mathcal{F} = \{f(x) = \mathbb{1}\{X_i \leq t\} : t \in \mathbb{R}\}$ . Partition  $\mathbb{R}$  into grids  $-\infty = t_0 < t_1 < \dots < t_m = \infty$  such that  $\mathbb{P}(t_i \leq X \leq t_{i+1}) < \epsilon$  for each  $i$ . Then the finitely many brackets  $[\mathbb{1}\{X_i \leq t_i\}, \mathbb{1}\{X_i \leq t_{i+1}\}]$  cover  $\mathcal{F}$  and are “size”  $\epsilon$  under  $P$ . So,  $\mathcal{N}_{[]}(\epsilon, \mathcal{F}, L_1(P)) < \infty$  for every  $\epsilon > 0$ . So  $\mathcal{F}$  is Glivenko-Cantelli (i.e, we have a uniform law of large numbers).

The requirement on the bracketing numbers can in general be hard. Would like a result for the covering numbers as well. This will make showing that some classes are Glivenko-Cantelli easier later on. Before doing so, we need to make a couple definitions:

**Definition 3.12** (Envelope). A class  $\mathcal{F}$  has envelope  $F$  if  $|f(x)| \leq F(x)$  for all  $x$  and all  $f \in \mathcal{F}$ .

**Definition 3.13** (Truncated Class). Let  $\mathcal{F}$  be a class of functions. Then the truncated class  $\mathcal{F}_M$  is given

$$\mathcal{F}_M = \{f(x)\mathbb{1}\{f \leq M\} : f \in \mathcal{F}\}.$$

**Definition 3.14** (P-Measurable Class). A class  $\mathcal{F}$  is  $P$ -measurable if  $\sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n f(x_i) \epsilon_i \right|$  is measurable with respect to the product measure on  $(\mathcal{X}^m, \mathcal{A}^m, P^n) \times (\mathcal{Z}, \mathcal{C}, Q)$ , where  $(\mathcal{Z}, \mathcal{C}, Q)$  denotes the probability space that the Rademachar random variables are defined on.

**Definition 3.15** ( $L_p(\mathbb{P}_n)$ -norm). We have that  $\|f - g\|_{L_1(P)} = \mathbb{E}_P \left[ |f(x) - g(x)|^p \right]^{1/p}$ , similarly we can define

$$\|f - g\|_{L_p(\mathbb{P}_n)} = \mathbb{E}_{\mathbb{P}_n} \left[ |f(x) - g(x)|^p \right]^{1/p}.$$

and through this define  $\mathcal{N}_{[]}(\epsilon, \mathcal{F}, L_p(\mathbb{P}_n))$ .

**Theorem 3.3** (Theorem 2.4.3, VdV&W). Let  $\mathcal{F}$  be a  $P$ -measurable class of measurable functions with envelope  $F$  such that  $\mathbb{P}^* F < \infty$ . If  $\log \mathcal{N}_{[]}(\epsilon, \mathcal{F}_M, L_1(\mathbb{P}_n)) = o_{P^*}(n)$  for every  $\epsilon$  and  $M > 0$ , then  $\|\mathbb{P}_n - P\|_{\mathcal{F}}^* \rightarrow 0$  almost surely and in mean.

*Proof.* Idea will be to apply the maximal inequality in Theorem 3.1.

*Step 1: Symmetrization.* First, we will apply symmetrization (Corollary 3.1)

$$\mathbb{E}^* \left[ \sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n f(X_i) - Pf(X_i) \right| \right] \leq 2 \cdot \mathbb{E}^* \left[ \sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right]$$

And then truncate the functions,  $f = f\mathbb{1}\{f \leq M\} + f\mathbb{1}\{f > M\}$ , apply triangle inequality, and bound the functions not in  $\mathcal{F}_M$  with the envelope  $F$ .

$$\begin{aligned} &\leq 2\mathbb{E}_X \mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] + 2\mathbb{E}^* [\epsilon_i F(X_i) \mathbb{1}\{F \geq M\}] \\ &= 2\mathbb{E}_X \mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] + 2P^* F(X_i) \mathbb{1}\{F \geq M\} \end{aligned}$$

Note the argument that allows us to replace the first outer expectation with iterated expectations over  $X$  and  $\epsilon$ : each of the functions in  $\mathcal{F}$  are measurable and  $\mathcal{F}_M$  is uniformly bounded, which means that the supremum will be measurable and bounded with probability 1 in any finite sample (with respect to the empirical measure/conditional on the  $X$  data).

Since  $P^* F < \infty$  we can choose  $M$  so that the term on the right is arbitrarily small.<sup>2</sup> That is, for any  $\delta > 0$

<sup>1</sup>This generalizes easily for a vector valued random variable

<sup>2</sup>I am sort of using  $P^*$  and  $\mathbb{E}_X^*$  interchangeably here, which I apologize for

we can pick  $M$  such that

$$\mathbb{E}^* \left[ \sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n f(X_i) - Pf(X_i) \right| \right] \leq \mathbb{E}_X \mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] + \delta.$$

*Step 2: Deal with the term that is conditional on  $\{X_i\}$ .* Let  $\mathcal{G}_\delta = \{g_1, \dots, g_{K(\delta)}\}$  be such that for every  $f \in \mathcal{F}_M$  there is a  $g \in \mathcal{G}_\delta$  such that  $\|f - g\|_{L_1(\mathbb{P}_n)} < \delta$ . Since  $\log \mathcal{N}(\delta, \mathcal{F}_M, L_1(\mathbb{P}_n)) = o_p(n)$ , we know that it is possible to pick a  $\mathcal{G}_\delta$  in this fashion with probability approaching 1. Note that:

- Cardinality of  $\mathcal{G}_\delta$ :  $|\mathcal{G}_\delta| = \mathcal{N}(\delta, \mathcal{F}_M, \|\cdot\|_{L_1(\mathbb{P}_n)})$ .
- Envelope of  $\mathcal{G}_\delta$ : by construction  $\mathcal{F}_M \leq M$  so we can assume that  $\mathcal{G}_\delta \leq M$ .

Then, for all  $f \in \mathcal{F}_M$  we have that, for some  $g \in \mathcal{G}_\delta$ :

$$\begin{aligned} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| &\leq \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i) \right| + \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i (f(X_i) - g(X_i)) \right| \\ &\leq \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i) \right| + \delta \end{aligned}$$

This gives us that

$$\mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] \leq \mathbb{E}_\epsilon \left[ \sup_{g \in \mathcal{G}_\delta} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i) \right| \right] + \delta.$$

*Step 3: Apply the Maximal Inequality.* We bound the first term in the last display using the maximal inequality in Lemma 3.2, for the particular case of the  $\psi_2$  Orlicz norm<sup>3</sup>: if  $D = \{f_1, \dots, f_M\}$  then

$$\mathbb{E} \left[ \sup_{f \in D} |f(X_i)| \right] \leq C \sqrt{1 + \log m}$$

for any  $C$  with  $\mathbb{E} \left[ \exp \left( \frac{f(X_i)}{C^2} \right) - 1 \right] \leq 1$  for all  $f \in D$ . In our setting we will apply this to the functions  $\frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i)$  for  $g \in \mathcal{G}_\delta$ , with the  $g(X_i)$  treated as fixed so that these are considered random variables in  $\epsilon_i$ . In our setting we can bound:

$$\mathbb{E}_\epsilon \left[ \sup_{g \in \mathcal{G}_\delta} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i) \right| \right] \leq C_\delta \sqrt{1 + \log \mathcal{N}(\delta, \mathcal{F}_M, \|\cdot\|_{L_1(\mathbb{P}_n)})}.$$

for such a  $C_\delta$  such that, for all  $g \in \mathcal{G}_\delta$

$$\mathbb{E}_\epsilon \left[ \exp \left( \left( \frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i) \right)^2 / C_\delta^2 \right) - 1 \right] \leq 1.$$

Hoeffding's inequality (Lemma 3.4) gives us that, for a general Rademacher process:

$$\mathbb{P}_\epsilon \left( \left| \sum_{i=1}^n \epsilon_i a_i \right| > x \right) \leq 2 \exp \left( -\frac{1}{2} \frac{x^2}{\|a\|^2} \right)$$

<sup>3</sup>We know that, in any finite sample, this Orlicz norm exists because our empirical expectation is bounded.

Where the norm above is the standard Euclidean norm. In our setting:

$$\mathbb{P}_\epsilon \left( \left| \sum_{i=1}^n \epsilon_i \frac{g(X_i)}{n} \right| > x \right) \leq 2 \exp \left( -\frac{1}{2} \frac{x^2}{n^{-2} \sum g(X_i)^2} \right)$$

As discussed above, we can uniformly bound  $\mathcal{G}_\delta$  by  $M$ . The exponential is negative so it is decreasing in the numerator and increasing in the denominator. This allows us to get:

$$\mathbb{P}_\epsilon \left( \left| \sum_{i=1}^n \epsilon_i \frac{g(X_i)}{n} \right| > x \right) \leq 2 \exp \left( -\frac{nx^2}{2M^2} \right)$$

Now apply Lemma 3.1. If  $\mathbb{P}(|X| > x) \leq Ke^{-Dx^2}$  then the  $\psi_2$ -Orlicz norm of  $X$  is less than  $\sqrt{(1+K)/D}$ . Using the above take  $K = 2$  and  $D = n/(2M^2)$  to get  $C_\delta = \sqrt{6M^2/n}$ . Putting this together with the original application of the maximal inequality towards the top of Step 3, we get:

$$\mathbb{E}_\epsilon \left[ \sup_{g \in \mathcal{G}_\delta} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i g(X_i) \right| \right] \leq \sqrt{6M^2/n + \log \mathcal{N}(\delta, \mathcal{F}_M, \|\cdot\|_{L_1(\mathbb{P}_n)})} / n$$

By assumption  $\log \mathcal{N}(\cdot)/n = o_P(1)$  and the first term under the square root is  $o(1)$  so that this whole thing is  $o_P(1)$ . All together, combining this with the result of Step 2, we have shown that, for any  $\delta > 0$ :

$$\mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] \leq \delta + o_P(1).$$

So that the whole thing  $(\mathbb{E}_\epsilon[\sup_{f \in \mathcal{F}_M} \dots])$  is  $o_P(1)$ .

*Step 4: Put all the parts together.*

By the symmetrization at the top of step 1, we have that, for every  $\delta > 0$

$$\mathbb{E} \left[ \sup_{\mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] \leq 2\mathbb{E}_X \mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] + \delta.$$

In Step 3, we showed that the inner expectation is  $o_P(1)$ . Combining this with the fact that  $\mathcal{F}_M \leq M$  gives us that<sup>4</sup>:

$$\mathbb{E}_X \mathbb{E}_\epsilon \left[ \sup_{f \in \mathcal{F}_M} \left| \frac{1}{n} \sum_{i=1}^n \epsilon_i f(X_i) \right| \right] = o(1).$$

which we can combine with Markov's inequality to get that

$$\sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{i=1}^n \{f(X_i) - Pf(X_i)\} \right| = o_P(1).$$

This shows that  $\|\mathbb{P}_n - P\|_{\mathcal{F}}^* \rightarrow 0$  in mean. From VdV&W: That it also converges almost surely follows from the fact that the sequence  $\|\mathbb{P}_n - P\|_{\mathcal{F}}^*$  is a reverse martingale with respect to a suitable filtration.<sup>5</sup>  $\square$

**Remark.** A couple comments on Theorem 3.3:

- Proof is harder than that using bracketing numbers (Theorem 3.2). However, the technique is much closer to what will be used for the Donsker Theorems.
- Note how the measurability is obtained using the  $\epsilon_i$  and conditioning on  $\{X_i\}$ .
- The conditions look cryptic, but we will find ways of verifying them.

<sup>4</sup>Convergence in probability to 0 implies convergence in distribution to 0 implies convergence in bounded moments

<sup>5</sup>This part may depend on i.i.d. I am not familiar with the martingale convergence theorems.

### 3.5 Donsker Theorems

This subsection follows section 2.5 in Van DerVaart and Wellner. In this subsection we will establish conditions for  $\mathcal{F}$  to be Donsker (Definition 3.4). We will present two main results, one that relies on the covering numbers (through a Uniform Entropy condition) and another using the bracketing numbers.

**Definition 3.16** (Uniform Entropy Condition). Let  $\mathcal{F}$  be a class of functions with envelope  $F$  and let  $\mathcal{Q}$  be the set of all finitely discrete probability measures on  $(\mathcal{X}, \mathcal{A})$ . We say that  $\mathcal{F}$  satisfies a uniform entropy bound if:

$$\int_0^\infty \sup_{Q \in \mathcal{Q}} \sqrt{\log(\epsilon \|F\|_{Q,2}, \mathcal{F}, L_2(Q))} d\epsilon < \infty \quad (\text{UEB})$$

Similarly to before define

$$\mathcal{F}_\delta = \{f - g : f, g \in \mathcal{F} \text{ and } \|f - g\|_{P,2} < \delta\} \quad (3.10)$$

$$\mathcal{F}_\infty^2 = \{(f - g)^2 : f, g \in \mathcal{F}\} \quad (3.11)$$

**Theorem 3.4** (Theorem 2.5.2 VdV&W). *Let  $\mathcal{F}$  be a class of measurable functions with envelope  $F$  that satisfies the uniform entropy bound, (UEB). Let the classes  $\mathcal{F}_\delta$  and  $\mathcal{F}_\infty^2$  also be  $P$ -measurable for every  $\delta > 0$ . If  $P^*F^2 < \infty$  then  $\mathcal{F}$  is  $P$ -Donsker.*

*Proof.* Because the envelope  $F$  has a bounded second moment we can apply CLT to get convergence of the marginals for any finite collection  $f_1, \dots, f_k$ . That is

$$(\mathbb{G}_n f_1, \dots, \mathbb{G}_n f_n) \xrightarrow{L} (\mathbb{G} f_1, \dots, \mathbb{G} f_k).$$

for some tight limit  $\mathbb{G}$ . By Theorem 2.5 it is now sufficient (and necessary) to show that  $\mathbb{G}_n(\mathcal{F})$  is asymptotically tight. We do this by way of Theorem 2.7, showing that  $\mathbb{G}_n$  is asymptotically  $\rho$ -equicontinuous and  $\mathcal{F}$  is totally bounded for some  $\rho$ .<sup>1</sup> That is, we want to show that there is some  $\rho$  semimetric with

$$\mathbb{P} \left( \sup_{\rho(f,g) < \delta} |\mathbb{G}_n f - \mathbb{G}_n g| > \epsilon \right) < \eta.$$

Goal will be to show this for  $\rho(f, g) = (P(f - g)^2)^{1/2}$ .

*Step 1: Use Symmetrization to apply Maximal Inequality.* Apply Markov's inequality and then Lemma 3.6 (or Corollary 3.1) to the class  $\sqrt{n}\mathcal{F}_\delta$  to get:

$$\begin{aligned} \mathbb{P} \left( \sup_{\rho(f,g) < \delta} |\mathbb{G}_n f - \mathbb{G}_n g| > \epsilon \right) &\leq \frac{1}{\epsilon} \cdot \mathbb{E} \left[ \sup_{\rho(f,g) < \delta} |\mathbb{G}_n f - \mathbb{G}_n g| \right] \\ &\leq \frac{2}{\epsilon} \cdot \mathbb{E}_X \mathbb{E}_\epsilon \left[ \sup_{\rho(f,g) < \delta} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \epsilon_i (f(x_i) - g(x_i)) \right| \right] \end{aligned} \quad (\text{D-0})$$

Note that the inside is measurable, so we can use iterated expectations. Recall by the maximal inequality (Theorem 3.1) if  $D$  is a set equipped with metric  $d$  and  $\mathbb{G}$  is a subgaussian process, then

$$\mathbb{E} \left[ \sup_{f,g \in D} |\mathbb{G} f - \mathbb{G} g| \right] \leq C \int_0^{\text{diam}(D)} \sqrt{\log \mathcal{N}(\epsilon, D, d)} d\epsilon.$$

<sup>1</sup>We know that the marginals of  $\mathbb{G}_n$  are asymptotically tight because they converge to a tight limit (Lemma 2.1)

where subgaussian is defined as  $\mathbb{P}(|\mathbb{G}f - \mathbb{G}g| > x) \leq 2 \exp(-\frac{1}{2}x^2/d^2(f, g))$ . Lemma 3.4 (Hoeffding's) gives us that the Rademacher process is subgaussian conditional on  $\{X_i\}$  for any class of functions  $\mathcal{F}$  equipped with the  $L_2(\mathbb{P}_n)$  norm.<sup>2</sup> This gives us that

$$\mathbb{E}_\epsilon \left[ \sup_{\rho(f, g) < \delta} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \epsilon_i (f(x_i) - g(x_i)) \right| \right] \lesssim \int_0^{\text{diam}(\mathcal{F}_\delta)} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}_\delta, \|\cdot\|_{L_2(\mathbb{P}_n)})} d\epsilon \quad (\text{D-1})$$

where note that the diameter on the RHS is calculated with respect to  $L_2(P_n)$  not the  $\rho(f, g) = \|f - g\|_{L_2(P)}$  on the right hand side.<sup>3</sup>

*Step 2: Make Sense of the Upper Bound.* Let  $\theta_n^2 := \text{diam}^2(\mathcal{F}_\delta) = \sup_{\rho(f, g) < \delta} \frac{1}{n} \sum_{i=1}^n (f(x_i) - g(x_i))^2$ . Let  $u := \epsilon / \|F\|_{L_2(\mathbb{P}_n)}$  and rewrite the above<sup>4</sup>

$$\begin{aligned} \int_0^{\text{diam}(\mathcal{F}_\delta)} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}_\delta, L_2(\mathbb{P}_n))} d\epsilon &= \int_0^{\theta_n} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}_\delta, L_2(\mathbb{P}_n))} d\epsilon \\ &= \|F\|_{\mathbb{P}_n, 2} \int_0^{\theta_n / \|F\|_{\mathbb{P}_n, 2}} \sqrt{\log \mathcal{N}(u \|F\|_{\mathbb{P}_n}, \mathcal{F}_\delta, L_2(\mathbb{P}_n))} du \end{aligned}$$

Since  $\mathbb{P}_n$  is a discrete probability measure

$$\leq \|F\|_{\mathbb{P}_n, 2} \int_0^{\theta_n / \|F\|_{\mathbb{P}_n, 2}} \sup_Q \sqrt{\log \mathcal{N}(u \|F\|_{Q, 2}, \mathcal{F}, \|\cdot\|_{L_2(Q)})} du$$

But, since  $\mathcal{F}_\delta \subseteq \mathcal{F}_\infty$  we get that  $\mathcal{N}(\epsilon, \mathcal{F}_\delta, L_2(Q)) \leq \mathcal{N}(\epsilon, \mathcal{F}_\infty, L_2(Q))$ . Also, see that  $\mathcal{N}(\epsilon, \mathcal{F}_\infty, L_2(Q)) \leq \mathcal{N}^2(\epsilon/2, \mathcal{F}, L_2(Q))$ . (Why?) In total:

$$\int_0^{\text{diam}(\mathcal{F}_\delta)} \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}_\delta, L_2(\mathbb{P}_n))} d\epsilon \leq \|F\|_{\mathbb{P}_n, 2} \int_0^{\theta_n / \|F\|_{\mathbb{P}_n, 2}} \sup_Q \sqrt{2 \log \mathcal{N}(u \|F\|_{Q, 2} / 2, \mathcal{F}, L_2(Q))} du \quad (\text{D-2})$$

*Step 3: Go Back to the Full Expectation.* Combining the inequality directly above and (D-1) and applying to the symmetrization inequality in (D-0), we get that

$$\mathbb{E} \left[ \sup_{\rho(f, g) < \delta} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^n \epsilon_i (f(x_i) - g(x_i)) \right| \right] \leq \mathbb{E} \left[ \|F\|_{\mathbb{P}_n, 2} \int_0^{\theta_n / \|F\|_{\mathbb{P}_n, 2}} \sup_Q \sqrt{2 \log \mathcal{N}(u \|F\|_{Q, 2} / 2, \mathcal{F}, L_2(Q))} du \right]$$

Where the expectations above are with respect to  $X$ . Apply Cauchy-Schwarz to upper bound the above by

$$\mathbb{E}_X \left[ \left( \int_0^{\theta_n / \|F\|_{\mathbb{P}_n, 2}} \sup_Q \sqrt{2 \log \mathcal{N}(u \|F\|_{Q, 2} / 2, \mathcal{F}, L_2(Q))} du \right)^2 \right]^{1/2} \mathbb{E}_X \left[ \|F\|_{\mathbb{P}_n, 2}^2 \right]^{1/2} \quad (\text{D-3})$$

Note that  $\mathbb{E}_X [\|F\|_{\mathbb{P}_n, 2}^2] = \mathbb{E}_X [n^{-1} \sum F^2(x_i)] \leq P^* F^2 < \infty$ . What is left is to show that the expectation of the integral in (D-3) converges to zero provided that  $\theta_n / \|F\|_{\mathbb{P}_n, 2} \rightarrow_{P^*} 0$ .

*Step 4: Figure out what is happening with  $\theta_n / \|F\|_{\mathbb{P}_n, 2}$ .* Note that  $\|F\|_{\mathbb{P}_n, 2}$  is bounded below by  $\|F_\star\|_{\mathbb{P}_n, 2}$  which converges almost surely to its expectation. Recall that

$$\theta_n^2 = \sup_{\rho(f, g) < \delta} \frac{1}{n} \sum_{i=1}^n (f(x_i) - g(x_i))^2 \leq \underbrace{\sup_{\rho(f, g) < \delta} \|(\mathbb{P}_n - P)(f - g)\|^2}_{= \|\mathbb{P}_n - P\|_{\mathcal{F}_\delta^2}} + \underbrace{\sup_{\rho(f, g) < \delta} P(f - g)^2}_{< \delta^2}.$$

<sup>2</sup>Note that

$$\left\| \left[ \frac{1}{\sqrt{n}} f(x_i) - \frac{1}{\sqrt{n}} g(x_i) \right]_{i=1}^n \right\|^2 = \frac{1}{n} \sum_{i=1}^n (f(x_i) - g(x_i))^2 = \|f - g\|_{L_2(\mathbb{P}_n)}^2.$$

<sup>3</sup>It also may be helpful to recall that  $\mathcal{F}_\delta = \{f - g : \rho(f, g) < \delta\}$

<sup>4</sup>Going to use  $L_2(\mathbb{P}_n)$  or just  $\|\cdot\|_{\mathbb{P}_n, 2}$  instead of  $\|\cdot\|_{L_2(\mathbb{P}_n)}$  to save some space. Also the empirical measure is bounded and  $F$  has bounded second outer moment so we know that  $\|F\|_{L_2(\mathbb{P}_2)} < \infty$  almost surely.

Since  $\mathcal{F}_\delta^2 \subseteq \mathcal{F}_\infty^2$  we want to show to show that  $\mathcal{F}_\infty^2$  is Glivenko-Cantelli. Theorem 3.3 gives that is enough to show that  $\log \mathcal{N}(\epsilon, \mathcal{F}_\infty^2, L_1(\mathbb{P}_n)) = o_{P^*}(n)$ .<sup>5</sup> For any pair of functions  $f, g \in \mathcal{F}_\infty$

$$\mathbb{P}_n|f^2 - g^2| = \mathbb{P}_n|(f - g)(f + g)| \leq \mathbb{P}_n|f - g|4F \leq 2\|F\|_{\mathbb{P}_{n,2}}\|f - g\|_{\mathbb{P}_{n,2}}.$$

where in the above we use that  $2F$  is an envelope for  $\mathcal{F}_\infty$ . This gives us that  $\mathcal{N}(\epsilon, \mathcal{F}_\infty^2, L_1(\mathbb{P}_n)) \leq \mathcal{N}(\epsilon/\|2F\|_{\mathbb{P}_{n,2}}, \mathcal{F}_\infty, L_2(\mathbb{P}_n))$ . Why? Suppose we cover  $\mathcal{F}_\infty^2$  with  $N$  balls of size  $\epsilon$ . By the inequalities above, we can find equivalent (centered at say,  $(f - g)/2$  instead of  $(f^2 - g^2)/2$ ) balls that will cover  $\mathcal{F}_\infty^2$  with radius  $\epsilon/\|F\|_{\mathbb{P}_{n,2}}$  in  $L_2(\mathbb{P}_n)$ . As argued above, we know that this is less than  $\mathcal{N}^2(\epsilon/4\|F\|_{L_2(\mathbb{P}_n)}, \mathcal{F}, L_2(\mathbb{P}_n))$  which we know has to be finite for any  $\epsilon$  in order for (UEB) to be satisfied. Since  $\mathcal{N}(\epsilon, \mathcal{F}_\infty, L_1(\mathbb{P}_n))$  is bounded by a constant, it's logarithm is surely  $o_{P^*}(n)$ .

So, combining with the display at the beginning of this set we have that

$$\theta_n^2 \leq \sup_{\rho(f,g) < \delta} \left| (\mathbb{P}_n - P)(f - g)^2 \right| + \delta^2 \rightarrow_{a.s.} \delta.$$

Together this gives us that

$$\frac{\theta_n}{\|F\|_{\mathbb{P}_{n,2}}} \leq \frac{\theta_n}{\|F_\star\|_{\mathbb{P}_{n,2}}} \rightarrow_{a.s.} \frac{\delta}{\|F_\star\|_{P,2}}. \quad (\text{D-4})$$

*Step 5: Put Together to get Asymptotic Equicontinuity.* Take  $C = (P^*F^2)^{1/2}$  and combine the inequalities in (D-1), (D-2), (D-3) with the convergence result in (D-4).

$$\begin{aligned} & \limsup \mathbb{P} \left( \sup_{\rho(f,g) < \delta} |\mathbb{G}_n f - \mathbb{G}_n g| > \epsilon \right) \\ & \leq \frac{1}{\epsilon} \limsup \mathbb{E} \left[ \|F\|_{\mathbb{P}_{n,2}} \int_0^{\theta_n/\|F\|_{\mathbb{P}_{n,2}}} \sup_Q \sqrt{2 \log \mathcal{N}(u\|F\|_{Q,2}/2, \mathcal{F}, L_2(Q))} du \right] \\ & \leq \frac{C}{\epsilon} \limsup \mathbb{E} \left[ \left( \int_0^{\theta_n/\|F\|_{\mathbb{P}_{n,2}}} \sup_Q \sqrt{2 \log \mathcal{N}(u\|F\|_{Q,2}/2, \mathcal{F}, L_2(Q))} du \right)^2 \right]^{1/2} \\ & \rightarrow_{a.s.} \frac{C}{\epsilon} \int_0^{\delta/\|F_\star\|_{P,2}} \sup_Q \sqrt{2 \log \mathcal{N}(u\|F\|_{Q,2}/2, \mathcal{F}, L_2(Q))} du \end{aligned}$$

However, by the uniform entropy bound in (UEB) the integral up to infinity in the above display is finite so the display above converges to 0 as  $\delta \downarrow 0$ . So we have verified that  $\mathbb{G}_n$  is asymptotically equicontinuous.

*Step 6: Verify that  $\mathcal{F}$  is totally bounded.* Finally what remains is to show that  $\mathcal{F}$  is totally bounded in  $L_2(P)$  (Definition 1.17). Take a sequence of discrete measures  $\mathbb{P}_n$  such that  $\|\mathbb{P}_n - P\|_{\mathcal{F}_\infty}$  converges to 0. Since we know that  $\mathcal{F}_\infty$  is Glivenko-Cantelli, this is always possible. Pick  $n$  large enough such that  $\|\mathbb{P}_n - P\|_{\mathcal{F}_\infty} < \delta^2$ . By triangle inequality

$$P(f - g)^2 = \mathbb{P}_n(f - g)^2 - (\mathbb{P}_n - P)(f - g)^2 \leq \frac{1}{n} \sum_{i=1}^n (f(x_i) - g(x_i))^2 + \|\mathbb{P}_n - P\|_{\mathcal{F}_\infty}.$$

This implies that  $\mathcal{F}$  is totally bounded under  $L_2(P)$  since we are totally bounded under  $L_2(\mathbb{P}_n)$  (Finite Envelope + Finite Measure).  $\square$

**Example 3.5** (Cells in  $\mathbb{R}$  are Donsker). Let  $X$  be a scalar and suppose that we want to show a functional CLT for

$$\mathbb{G}_n(t) = \frac{1}{\sqrt{n}} \sum_{i=1}^n \{ \mathbb{1}[X_i \leq t] - P(X \leq t) \}.$$

<sup>5</sup>Inherits bounded envelope by triangle inequality. If  $F$  bounds  $\mathcal{F}$ , then  $4F^2$  bounds  $\mathcal{F}_\infty^2$ .

<sup>6</sup>By Cauchy-Schwarz:  $\frac{1}{n} \sum_{i=1}^n f(x_i)g(x_i) \leq \left[ \frac{1}{n} \sum_{i=1}^n f^2(x_i) \right]^{1/2} \left[ \frac{1}{n} \sum_{i=1}^n g^2(x_i) \right]^{1/2}$

Main challenge is showing the uniform entropy bound (UEB). Recall that for any  $\|\cdot\|$ ,  $\mathcal{N}(\epsilon, \mathcal{F}, \|\cdot\|) \leq \mathcal{N}_{[]} (2\epsilon, \mathcal{F}, \|\cdot\|)$ . Apply the above to  $\|\cdot\|_{Q,2}$ . Partition  $\mathbb{R}$  into  $-\infty = t_0 < t_1 < \dots < t_k = \infty$  such that  $\mathbb{P}(t_i \leq X \leq t_{i+1}) \leq 4\epsilon^2$ . These cover  $\mathcal{F} = \{f(x) = \mathbb{1}\{x \leq t\}, t \in \mathbb{R}\}$ . Further

$$\mathbb{E} \left[ \left( \mathbb{1}[X \leq t_i] - \mathbb{1}[X \leq t_{i+1}] \right)^2 \right]^{1/2} = \mathbb{P}(t_i \leq X \leq t_{i+1})^{1/2} = 2\epsilon.$$

In order to cover  $\mathcal{F}$  we need  $\lceil 1/4\epsilon^2 \rceil \leq 2\epsilon^2$ . This process can be done for any probability measure  $Q$  so that if  $\epsilon < 1$ :

$$\mathcal{N}(\epsilon, \mathcal{F}, L_2(Q)) \leq \mathcal{N}_{[]} (2\epsilon, \mathcal{F}, L_2(Q)) \leq 2/\epsilon^2 \wedge 1.$$

If  $\epsilon \geq 1$  only one ball is needed. Then, since  $F(x) = 1$  and if  $\epsilon > 1$  one ball is enough (and  $\log 1 = 0$ ):

$$\begin{aligned} \int_0^\infty \sup_Q \sqrt{\log \mathcal{N}(\epsilon \|F\|_{Q,2}, \mathcal{F}, L_2(Q))} d\epsilon &= \int_0^1 \sup_Q \sqrt{\log \mathcal{N}(\epsilon, \mathcal{F}, L_2(Q))} d\epsilon \\ &\leq \int_0^1 \sqrt{\log(2/\epsilon)} d\epsilon \end{aligned}$$

This is easily Donsker by Theorem 3.4 and in fact the argument hold for cells in  $\mathbb{R}^K$ . However, note that this seems like cheating a bit, since we are using the bracketing numbers to get the covering numbers.

We now want to show a Donsker Theorem using bracketing numbers. The proof is more involved than for the Glivenko-Cantelli Theorem (Theorem 3.2) using bracketing numbers, so we may not get too far into it here.

To show this theorem we make minor use of the following related statements from VdV&W.

**Lemma 3.7** (Problem 2.5.5 VdV&W). *If  $X$  is a positive random variable,  $\|X\|_2^2 \leq \sup_{t>0} t \mathbb{E} X \mathbb{1}\{X > t\} \leq 2\|X\|_2^2$ .*

**Lemma 3.8** (Problem 2.5.6 VdV&W). *Any random variable  $X$  with a finite second moment satisfies  $\mathbb{E}|X|\{X > t\} = o(t^{-1})$  as  $t \rightarrow \infty$ .*

**Lemma 3.9** (Equation 2.5.5 VdV&W). *For a finite set  $\mathcal{F}$  of cardinality  $\mathcal{F} \geq 2$ ,*

$$\mathbb{E}\|\mathbb{G}_n\|_{\mathcal{F}} \lesssim \max_f \frac{\|f\|_\infty}{\sqrt{n}} \log |\mathcal{F}| + \max_f \|f\|_{P,2} \sqrt{\log |\mathcal{F}|}.$$

**Theorem 3.5** (Donsker Theorem for Bracketing Numbers). *Let  $\mathcal{F}$  be a class of measurable functions with an envelope  $F$  such that  $P^*F^2 < \infty$  and*

$$\int_0^\infty \sqrt{\log \mathcal{N}_{[]}(\epsilon, \mathcal{F}, L_2(P))} d\epsilon < \infty \tag{3.12}$$

*then  $\mathcal{F}$  is Donsker.*

*Proof.* The proof of this is roughly based on the steps in Theorem 2.5.6 in VanDerVaart and Wellner. I attempt to replicate the argument below:

For each  $q \in \mathbb{N}$  there is a partition  $\mathcal{F} = \bigcup_{i=1}^{N_q} \mathcal{F}_{qi}$  of  $\mathcal{F}$  into  $N_q$  disjoint subsets such that

$$\begin{aligned} \sum_{i=1}^{\infty} 2^{-q} \sqrt{\log N_q} &< \infty \\ \left\| \left( \sup_{f,g \in \mathcal{F}_{qi}} |f - g| \right)^* \right\|_{P,2} &< 2^{-q} \\ \sup_{f,g \in \mathcal{F}_{qi}} \|f - g\|_{P,2} &< 2^{-q} \end{aligned}$$

To see this, cover  $\mathcal{F}$  with a minimal numbers of  $L_2(P)$  balls and  $L_2(P)$  brackets of size  $2^{-q}$ , disjointify and take the intersection of the two partitions. By definition of the  $2^{-q}$  balls and  $2^{-q}$  brackets, the last two conditions hold. To see that the first condition holds note that the integral of the bracketing number being finite implies that the integral of the covering number is finite, and that  $\mathcal{N}_{[]}^*$  and  $\mathcal{N}$  are decreasing in  $\epsilon$ . For any decreasing function  $f$  it is clear that

$$\sum_{i=1}^n 2^{-q} f(q) \leq \int_0^\infty f(q) dq.$$

which gives us the first condition. This sequence of partitions can, without loss of generality, be chosen as successive refinements.<sup>7</sup>

For each  $q$  choose a fixed element  $f_{qi}$  from each partitioning set  $\mathcal{F}_{qi}$  and define  $\pi_q f = f_{qi}$  if  $f \in \mathcal{F}_{qi}$ . Further define  $\Delta_q f = \sup_{f, g \in \mathcal{F}_{q,i}} |f - g|$  if  $f \in \mathcal{F}_{qi}$ .

Note that  $\pi_q f$  and  $\Delta_q f$  take on one of  $N_q$  values as  $f$  ranges through  $\mathcal{F}$ . In view of Theorem 2.6 it suffices to show that the sequence  $\|\mathbb{G}_n(f - \pi_{q_0} f)\|_{\mathcal{F}}$  converges in probability to zero as  $n \rightarrow \infty$  for an arbitrary  $q_0$  and then take  $q_0 \rightarrow \infty$ .

Define for each fixed  $n$  and  $q \geq q_0$  the following numbers and indicator-type functions:

$$\begin{aligned} a_q &= 2^{-q} / \sqrt{\log N_{q+1}} \\ A_{q-1} f &= \mathbf{1}\{\Delta_{q_0} f \leq \sqrt{n} a_{q_0} \wedge \cdots \wedge \Delta_{q-1} f \leq \sqrt{n} a_{q-1}\} \\ B_q f &= \mathbf{1}\{\Delta_{q_0} f \leq \sqrt{n} a_{q_0} \wedge \cdots \wedge \Delta_{q-1} f \leq \sqrt{n} a_{q-1} \wedge \Delta_q f > \sqrt{n} a_q\} \\ B_{q_0} &= \mathbf{1}\{\delta_{q_0} f > \sqrt{n} a_{q_0}\} \end{aligned}$$

Note that  $A_q f$  and  $B_q f$  are constant in  $f$  on each of the partitioning sets  $\mathcal{F}_{qi}$  at level  $q$  because the partitions are nested.<sup>8</sup>

Now, pointwise in  $x$ , decompose

$$f - \pi_{q_0} f = (f - \pi_{q_0} f) B_{q_0} f + \sum_{q=q_0+1}^{\infty} (f - \pi_q f) B_q f + \sum_{q=q+1}^{\infty} (\pi_q f - \pi_{q-1} f) A_{q-1} f \quad (\text{B-1})$$

Here note that we are essentially decomposing the event space into  $B_{q_0}$  and  $B_{q_0}^c = A_{q_0}$ . We can think of  $B_q$  as  $f$  being “between”  $A_{q-1}$  and  $A_q$ . That is, if all the conditions for  $B_q$  hold except for the last one, then  $A_{q-1}$  is equal to 1 and  $B_q$  is equal to zero. Conversely if  $B_q$  is equal to one, then all the conditions for  $A_q$  hold except for the last one ( $\Delta_q f \leq \sqrt{n} a_q$ ) so  $A_q$  is equal to zero and  $B_q$  is equal to one. Equivalently  $A_q + B_q = A_{q-1}$  or  $A_{q-1} - A_q = B_q$ . Combine this with the fact that sets indicated  $A_q$  are nested and telescope to get the decomposition above.

<sup>7</sup>To see this, construct a sequence of partitions  $\mathcal{F} = \bigcup_{i=1}^{\bar{N}_q} \bar{\mathcal{F}}_{qi}$  without this property. Next, take the partition at stage  $q$ ,  $\mathcal{F} = \bigcup_{i=1}^{\bar{N}_q} \mathcal{F}_{qi}$  to consists of all intersections of the form  $\bigcap_{p=1}^q \bar{\mathcal{F}}_{p, i_p}$  (basically take the intersection of all partitions up till  $q$ ) so that  $|N_q| = \prod_{p=1}^q \bar{N}_p$ . Using the inequality  $(\log \prod \bar{N}_p)^{1/2} \leq \sum (\log \bar{N}_p)^{1/2}$  we get that:

$$\begin{aligned} \sum_{q=1}^{\infty} 2^{-q} \sqrt{\log N_q} &\leq \sum_{q=1}^{\infty} 2^{-q} \sum_{p=1}^q \log \sqrt{\bar{N}_p} \\ &= \sum_{q=1}^{\infty} 2^{-q} \sum_{p=1}^{\infty} 2^{-p} \sqrt{\log \bar{N}_p} \\ &< \infty \end{aligned}$$

The equality is a bit difficult to see but follows from the preceding line after rewriting the double summation as a triangular array. To simplify, consider an infinite sequence  $\{a_i\}_{i=1}^{\infty}$ . Then  $\sum_{i=1}^{\infty} 2^{-i} \sum_{j=1}^i a_i = a_1 + \frac{1}{2}(a_1 + a_2) + \frac{1}{2^2}(a_1 + a_2 + a_3) + \dots$ . Rearrange to get the result. This gives us that the first condition still holds for the new nesting sequence of partitions. The second and third conditions trivially still hold as the new partitions are finer than the previous ones.

<sup>8</sup>Recall that  $\Delta_q f$  is the same for all elements in  $\mathcal{F}_{q,i}$  and that  $\mathcal{F}_{qi} \subset \mathcal{F}_{(q-1)i}$

Now we will apply the empirical process  $\mathbb{G}_n = \sqrt{n}(\mathbb{P}_n - P)$  to each of the terms in (B-1) and take the suprema over  $f \in \mathcal{F}$ . We will show that each of the resulting 3 variables converge to zero in probability and then take  $q_0 \rightarrow \infty$ .

First, since  $|f - \pi_{q_0}f|B_{q_0}f \leq 2F\mathbb{1}\{2F > \sqrt{n}a_{q_0}\}$  one has that<sup>9</sup>

$$\mathbb{E}^* \|\mathbb{G}_n(f - \pi_{q_0}f)B_{q_0}f\|_{\mathcal{F}} \leq 4\sqrt{n}P^*F\mathbb{1}\{2F > \sqrt{n}a_{q_0}\}.$$

The right hand side converges to zero as  $n \rightarrow \infty$  by Lemma 3.8 because  $F$  has a finite second outer moment.

By applying Lemma 3.7 and noting that  $B_qf \leq \mathbb{1}\{\Delta_qf > \sqrt{n}a_q\}$ :

$$\sqrt{n}a_qP\Delta_qfB_qf \leq \sqrt{n}a_qP\Delta_qf\mathbb{1}\{\Delta_qf > \sqrt{n}a_q\} \leq 2\|\Delta_qf\|_2^2 \leq 22^{-2q}.$$

Applying once that  $\Delta_{q-1}fB_qf$  is bounded by  $\sqrt{n}a_{q-1}$  for  $q > q_0$ , multiplying and dividing by  $a_q$ , and applying the inequality from above, we obtain the that inequality that we will need below:

$$P(\Delta_qfB_qf)^2 \leq \sqrt{n}a_{q-1}P\Delta_qf\mathbb{1}\{\Delta_qf > \sqrt{n}a_q\} \leq 2\frac{a_{q-1}}{a_q}2^{-2q}.$$

And now applying the triangle inequality, using that  $|ab| = |a||b|$  for  $a, b \in \mathbb{R}$ :

$$\mathbb{E}^* \left\| \sum_{q=q_0+1}^{\infty} \mathbb{G}_n(f - \pi_q)fB_qf \right\|_{\mathcal{F}} \leq \sum_{q=q_0+1}^{\infty} \mathbb{E}^* \|\mathbb{G}_n\Delta_qfB_qf\|_{\mathcal{F}}$$

Now applying Lemma 3.9. Note that 1) the implicit constant in the inequality can be taken to be universal by the nesting property of the subsets, 2) that  $\Delta_qfB_qf \leq \sqrt{n}a_{q-1}$ , the bounds derived above, and 3) that the supremum is taken over  $N_q$  functions at each level  $q$ :

$$\lesssim \sum_{q=q_0+1}^{\infty} a_{q-1} \log N_q + 2^{-q} \sqrt{2\frac{a_{q-1}}{a_q}} \sqrt{\log N_q}$$

Note that  $a_q$  is decreasing in  $q$  (as  $q$  increases the top of the fraction is getting smaller and the bottom of the fraction is getting larger) so that the quotient can be replaced by it's square. Now use the definition of  $a_q$  to bound this sum:

$$\lesssim \sum_{q=q_0+1}^{\infty} 2^{-q} \sqrt{\log N_q}$$

This bound is independent of  $n$  and converges to zero as  $q_0 \rightarrow \infty$ .

To bound the third term note that there are at most  $N_q$  functions  $(\pi_q - \pi_{q-1})f$ <sup>10</sup> and at most  $N_{q-1}$  functions  $A_{q-1}f$ . Since the partitions are nested ( $\mathcal{F}_{q_i} \subset \mathcal{F}_{q-1,i}$ ), the function  $|\pi_qf - \pi_{q-1}f|A_{q-1}f$  is bounded by  $\Delta_{q-1}fA_{q-1}f \leq \sqrt{n}a_{q-1}$ . Also by nesting, the  $L_2(P)$  norm of  $\pi_qf - \pi_{q-1}f$  is bounded by  $2^{-(q-1)}$ . Apply the inequality in Lemma 3.9 to get

$$\mathbb{E}^* \left\| \sum_{q=q_0+1}^{\infty} \mathbb{G}_n(\pi_q - \pi_{q-1})fA_{q-1}f \right\|_{\mathcal{F}} \lesssim \sum_{q=q_0+1}^{\infty} a_{q-1} \log N_q + 2^{-q} \sqrt{\log N_q}.$$

As before, this upper bound is independent of  $n$  and converges to zero as  $q_0 \rightarrow \infty$ .

Putting this all together we get that as  $n, q_0 \rightarrow \infty$

$$\mathbb{E}^* \sup_{f, g \in \mathcal{F}} |f - g| \leq 2E^* \|f - \pi_{q_0}f\|_{\mathcal{F}} \rightarrow 0.$$

<sup>9</sup>Recall the definition of the " $\mathcal{F}$ " norm, pull out the  $\sqrt{n}$ , apply triangle inequality and note that  $\mathbb{E}^*\mathbb{P}_nF \leq \mathbb{E}^*F$  because  $(S+T)^* \leq S^* + T^*$  for any functions  $S, T$ .

<sup>10</sup>each  $\pi_q$  has a specific  $\pi_{q-1}$  attached to it

which allows us to apply Theorem 2.6 and establish asymptotic equicontinuity. Because the envelope has finite second outer moment we can apply CLT to the marginals to get convergence to a tight distribution and apply Theorem 2.5 to get weak convergence of the whole process  $\mathbb{G}_n$ .  $\square$

**Remark** (Comments on Donsker Theorems). Note that the integral in the bracketing Donsker Theorem above does not require taking the supremum over all finitely discrete probability measures  $Q$ , instead we only deal with the underlying measure  $P$ . The idea here is the bracketing gives us more control on the arguments.

Also, note that there are no measurability concerns for the bracketing Donsker theorem. This is because we did not have to use symmetrization, instead relying on Lemma 3.9.

**Remark** (Summary: Glivenko-Cantelli vs. Donsker). Conditions for:

Glivenko-Cantelli:

- If  $\mathcal{N}_{[]}(\epsilon, \mathcal{F}, L_1(P)) < \infty$  for every  $\epsilon$  then  $\mathcal{F}$  is (P)-Glivenko-Cantelli.
- If  $\mathcal{F}$  is P-measurable with envelope  $F$  satisfying  $P^*F < \infty$  and for every  $M, \epsilon > 0$  we have that  $\log \mathcal{N}(\epsilon, \mathcal{F}_M, L_1(\mathbb{P}_n)) = o_{P^*}(n)$  then  $\mathcal{F}$  is (P)-Glivenko-Cantelli.

Donsker:

- If  $\mathcal{F}$  has envelope  $F$  with  $P^*F^2 < \infty$  and

$$\int_0^\infty \sqrt{\log \mathcal{N}_{[]}(\epsilon, \mathcal{F}, L_2(P))} d\epsilon < \infty.$$

then  $\mathcal{F}$  is Donsker.

- If  $\mathcal{F}$  has envelope  $F$  with  $P^*F^2 < \infty$ ,  $\mathcal{F}_\infty^2$  and  $\mathcal{F}_\delta$  are P-measurable for every  $\delta$  and the (UEB) is satisfied, that is

$$\int_0^\infty \sup_Q \sqrt{\log \mathcal{N}(\epsilon \|F\|_{Q,2}, \mathcal{F}, L_2(Q))} d\epsilon < \infty.$$

then  $\mathcal{F}$  is Donsker.

The bracketing numbers give you pointwise control of functions between the brackets, this gives us cleaner conditions for Glivenko-Cantelli and Donsker that depend only on the true measure. The covering number proofs require symmetrization and then applying Fubini's theorem, so we need measurability assumptions. The tradeoff is that bracketing numbers are larger than covering numbers, so the conditions may be harder to satisfy.

We have now reduced the conditions that we need for uniform convergence to conditions in terms of bracketing/covering numbers. Next we will turn to verifying these conditions and applying the uniform convergence results.

### 3.6 Covering Numbers

This section roughly covers section 2.6 in Van Der Vaart and Wellner.

Recall that for the covering Donsker Theorem, Theorem 3.4, we require the uniform entropy bound:

$$\int_0^\infty \sup_{Q \in \mathcal{Q}} \sqrt{\log \mathcal{N}(\epsilon \|F\|_{Q,2}, \mathcal{F}, L_2(Q))} d\epsilon < \infty. \quad (\text{UEB})$$

where the supremum under the integral is taken over the set of all finitely discrete probability measures  $\mathcal{Q}$ . If we can show that  $\mathcal{F}$  is such that  $\sup_Q \log \mathcal{N}(\epsilon \|F\|_{Q,2}, \mathcal{F}, L_2(Q)) \lesssim \left(\frac{1}{\epsilon}\right)^{2-\delta}$  for some  $\delta > 0$  then we are fine as the square root of this will integrate to a finite number. In fact, we will often be able to verify a much stronger condition, that:

$$\sup_Q \mathcal{N}(\epsilon \|F\|_{Q,2}, \mathcal{F}, L_2(Q)) \leq K \left(\frac{1}{\epsilon}\right)^V, \quad 0 < \epsilon < 1.$$

### 3.6.1 VC Classes of Sets

A typical way to show that a class of sets  $\mathcal{F}$  satisfies the (UEB) will be to show that it has a limited “VC-Dimension”, where “VC” stands for Vapnick and Cervonenkis. What does this mean?

Let  $\mathcal{C}$  be a collection of subsets of some set  $\mathcal{X}$ , that is  $\mathcal{C} \subseteq 2^{\mathcal{X}}$ . An arbitrary set of points  $\{x_1, \dots, x_n\}$  possesses  $2^n$  subsets.

**Definition 3.17** (Picking Out). Let  $A \subset \{x_1, \dots, x_n\}$ . The collection  $\mathcal{C}$  picks out  $A$  if  $A = C \cap \{x_1, \dots, x_n\}$  for some  $C \in \mathcal{C}$ . We define the number of subsets of  $\{x_1, \dots, x_n\}$  picked out by  $\mathcal{C}$  as

$$\Delta_n(\mathcal{C}, x_1, \dots, x_n) = \# \{C \cap \{x_1, \dots, x_n\} : C \in \mathcal{C}\} \quad (3.13)$$

**Definition 3.18** (Shattering). A collection  $\mathcal{C}$  shatters  $\{x_1, \dots, x_n\}$  if it can pick out all of its  $2^n$  subsets.

**Definition 3.19** (VC Index). The VC-Index,  $V(\mathcal{C})$  is the smallest  $n \in \mathbb{N}$  such that *no* set of size  $n$  is shattered by  $\mathcal{C}$ . Equivalently

$$V(\mathcal{C}) = \inf \left\{ n : \max_{x_1, \dots, x_n} \Delta_n(\mathcal{C}, x_1, \dots, x_n) < 2^n \right\} \quad (3.14)$$

**Definition 3.20** (VC Class). A collection  $\mathcal{C}$  of measurable sets is called VC Class if  $V(\mathcal{C}) < \infty$ .

**Remark.** Notice that in the Definition of the VC Index, we require that *no* set of size  $n$  is shattered by  $\mathcal{C}$  rather than requiring that  $n$  be the smallest number such that there exists *any* set of size  $n$  that is not shattered by  $\mathcal{C}$ .

**Example.** Suppose  $\mathcal{C} = \{(-\infty, c] : \text{for some } c \in \mathbb{R}\}$ . Then any set  $\{x_1\}$  has subsets  $\emptyset$  and  $\{x_1\}$ . For  $\emptyset$  we have that  $\emptyset \subset (-\infty, c] \cap \{x_1\}$  for any  $c < x_1$  while for  $\{x_1\}$  we have that  $\{x_1\} \subseteq (-\infty, c] \cap \{x_1\}$  for any  $c \geq x_1$ . Thus we have that  $\mathcal{C}$  shatters any single element subset of  $\mathbb{R}$ .

However, take a two element subset  $\{x_1, x_2\} \subset \mathbb{R}$ . Without loss of generality take  $x_1 < x_2$ . There are four subsets to consider,  $\emptyset, \{x_1\}, \{x_2\}, \{x_1, x_2\}$ . We can see that there is no set  $C \in \mathcal{C}$  such that  $C \cap \{x_1, x_2\} = \{x_2\}$ , if we take  $C = (-\infty, c]$  for some  $c < x_2$  we get that  $C \cap \{x_1, x_2\} = \{x_1\}$  whereas if we take  $C = (-\infty, c]$  for some  $c \geq x_2$  we get that  $C \cap \{x_1, x_2\} = \{x_1, x_2\}$ . This exhausts all sets in  $\mathcal{C}$ .

Since  $\{x_1, x_2\}$  is arbitrary, we can conclude that the VC Index of  $\mathcal{C}$  is two,  $V(\mathcal{C}) = 2$ .

**Example.** Let  $\mathcal{C}_1 = \{(a, b] : a < b \text{ for } a, b \in \mathbb{R}\}$ . Note that this collection is larger than the collection from the prior example. Now however, given a set  $\{x_1, x_2\}$  with  $x_1 < x_2$  we can pick out  $\{x_2\}$  with the set  $(x_1, x_2] \in \mathcal{C}_1$ .

However, now consider a three element subset  $\{x_1, x_2, x_3\}$ . Without loss of generality suppose  $x_1 < x_2 < x_3$ . We will try to pick out the set  $\{x_1, x_3\}$ . Consider any set  $C \in \mathcal{C}_1$  such that  $\{x_1, x_3\} \subset C$ , a necessary condition for  $\{x_1, x_3\} = C \cap \{x_1, x_2, x_3\}$ . The set  $C$  is of the form  $(a, b]$  for some  $a < x_1$  and  $b \geq x_3$ . However, this means that  $x_2 \in C$ . So, we cannot pick out  $\{x_1, x_3\}$  with  $\mathcal{C}_1$ .

Since we can pick out one and two element subsets of  $\mathbb{R}$  with  $\mathcal{C}_1$ , but not arbitrary three element subsets, we get that  $V(\mathcal{C}_1) = 3$ .

**Lemma 3.10** (Lemma 2.6.2 VdV&W). Let  $\{x_1, \dots, x_n\}$  be arbitrary points in  $\mathcal{X}$  and  $\mathcal{C}$  some collection of subsets of  $\mathcal{X}$ . Then the total number of subsets picked out by  $\mathcal{C}$ ,  $\Delta_n(\mathcal{C}, x_1, \dots, x_n)$  picked out by  $\mathcal{C}$  is bounded above by the total number of subsets of  $\{x_1, \dots, x_n\}$  shattered by  $\mathcal{C}$ .

*Proof.* Without loss of generality assume that every  $C \in \mathcal{C}$  is a subset of the given set of points so that  $\Delta_n(\mathcal{C}, x_1, \dots, x_n)$  is the cardinality of  $\mathcal{C}$ .

Call the class  $\mathcal{C}$  *hereditary* if it is closed under subsetting. That is  $C \in \mathcal{C}$  and  $B \subset C \implies B \in \mathcal{C}$ . Each of the sets in a hereditary collection of sets is shattered<sup>1</sup> so that a hereditary collection shatters at least

<sup>1</sup>For any  $B \subset C$ ,  $B \in \mathcal{C}$  and  $B \cap C = B$ .

$|\mathcal{C}|$  sets and the assertion of the lemma is certainly true for hereditary collections.<sup>2</sup> The goal now will be to show that an arbitrary collection  $\mathcal{C}$  can be transformed into a hereditary collection without changing its cardinality or increasing the number of shattered sets.

Given  $1 \leq i \leq n$  and  $C \in \mathcal{C}$  define the set

$$T_i(C) = \begin{cases} C \setminus \{x_i\} & \text{if } C \setminus \{x_i\} \notin \mathcal{C} \\ C & \text{otherwise} \end{cases}$$

The map  $T_i(x)$  is injective (one-to-one) so the collections  $\mathcal{C}$  and  $T_i(\mathcal{C}) = \{T_i(C), C \in \mathcal{C}\}$  have the same cardinalities.<sup>3</sup> Furthermore, every subset  $A \subset \{x_1, \dots, x_n\}$  that is shattered by  $T_i(\mathcal{C})$  is shattered by  $\mathcal{C}$ . To see this note that if  $x_i \notin A$  then  $\{\mathcal{C} \cap A\} = \{T_i(\mathcal{C}) \cap A\}$ . Conversely if  $x_i \in A$  and  $A$  is shattered by  $T_i(\mathcal{C})$  then for every  $B \subset A$  there is a  $C \in \mathcal{C}$  with  $B \cup \{x_i\} = T_i(C) \cap A$ .<sup>4</sup> This implies that  $x_i \in T_i(C)$  so that  $T_i(C) = C$ . This in turns gives that  $C \setminus \{x_i\} \in \mathcal{C}$  since otherwise  $T_i$  would not have a fixed point at  $C$ . Thus both  $B \cup \{x_i\}$  and  $B \setminus \{x_i\} = (C \setminus \{x_i\}) \cap A$  are picked out by  $\mathcal{C}$ . One of these sets equals  $B$ .

So the assertion of the lemma is true for  $\mathcal{C}$  if it is true for  $T_i(\mathcal{C})$ . Furthermore the assertion of the lemma is true for  $\mathcal{C}$  if it is true for  $T(\mathcal{C})$  where  $T = T_1 \circ T_2 \circ \dots \circ T_n$ ; by repeatedly applying the argument above we have that if a set is shattered by  $T(\mathcal{C})$  it is shattered by  $\mathcal{C}$ . Apply  $T$  repeatedly until the collection of sets does not change anymore. This happens after at most  $\sum_{C \in \mathcal{C}} |\mathcal{C}|$  steps (finite) since  $\sum_{C \in \mathcal{C}} |T_i(C)| < \sum_{C \in \mathcal{C}} |\mathcal{C}|$  whenever the collections  $T_i(\mathcal{C})$  and  $\mathcal{C}$  are different<sup>5</sup>. The collection  $\mathcal{D}$  obtained in this manner has the property that  $D \setminus \{x_i\} \in \mathcal{D}$  for every  $D \in \mathcal{D}$  and every  $x_i$ . So  $\mathcal{D}$  is hereditary.  $\square$

**Corollary 3.2** (Corollary 2.6.3 VdV&W). *For a VC-class of sets of index  $V(\mathcal{C})$  one has*

$$\max_{x_1, \dots, x_n} \Delta_n(\mathcal{C}, x_1, \dots, x_n) \leq \sum_{j=0}^{V(\mathcal{C})-1} \binom{n}{j}.$$

Consequently, the numbers on the left hand side grow polynomially of order at most  $O(n^{V(\mathcal{C})-1})$  as  $n \rightarrow \infty$ .

*Proof.* The RHS of the corollary above is the number of subsets of size at most  $V(\mathcal{C}) - 1$ . A VC-class shatters no set of  $V(\mathcal{C})$  points. All shattered sets are of size at most  $V(\mathcal{C}) - 1$ . The number of shattered sets gives an upper bound on  $\Delta_n$  by Lemma 3.10.  $\square$

**Theorem 3.6** (Theorem 2.6.4 VdV&W). *There exists a universal constant  $K$  such that, for any VC-class  $\mathcal{C}$  of sets, any probability measure  $Q$ , any  $r \geq 1$  and  $0 < \epsilon < 1$ ,*

$$\mathcal{N}(\epsilon, \mathcal{C}, L_r(Q)) \leq KV(\mathcal{C})(4e)^{V(\mathcal{C})} \left(\frac{1}{\epsilon}\right)^{r(V(\mathcal{C})-1)} \quad (3.15)$$

*Proof.* The proof of this Theorem takes some 3 pages in VanDerVaart so I am leaving it for now. It can be found on pages 137-139.  $\square$

**Remark.** For practical purposes, if  $V(\mathcal{G}) < \infty$ , then  $\sup_{Q \in \mathcal{Q}} \log \mathcal{N}(\epsilon, \mathcal{G}, L_2(Q)) \lesssim \log\left(\frac{1}{\epsilon}\right)$  which will mean that the (UEB) is satisfied.

<sup>2</sup>Taking a look at (3.13) we see that all sets picked out by  $\mathcal{C}$  are all subsets of elements of  $\mathcal{C}$ . Since all subsets of elements of  $\mathcal{C}$  are also elements of  $\mathcal{C}$ , the number of sets picked out by  $\mathcal{C}$  is bounded by the number of sets in  $\mathcal{C}$ . Every element of  $\mathcal{C}$  is clearly shattered by  $\mathcal{C}$  which gives the statement.

<sup>3</sup>Recall that  $\Delta_n(\mathcal{C}, x_1, \dots, x_n) = |\mathcal{C}|$  since by assumption (without loss of generality) every  $C \in \mathcal{C}$  is a subset of the given set of points. This holds as well for  $T_i(\mathcal{C})$

<sup>4</sup>This is just because  $B \cup \{x_i\} \subset A$  and  $A$  is shattered by  $T_i(\mathcal{C})$

<sup>5</sup>We can think of repeatedly applying  $T$  as “pruning” the collection  $\mathcal{C}$ , removing elements from sets whose subsets are not contained in  $\mathcal{C}$ .

**Example.** Suppose  $\mathcal{G}$  is a VC-class, that is the functions  $\mathbb{1}_G$  are measurable for  $G \in \mathcal{G}$  and  $V(\mathcal{G}) < \infty$ . Since this set of indicator functions is bounded by 1, this class is clearly Donsker. In the example above, we showed that the set  $\mathcal{G} = \{(a, b] : a < b, a, b \in \mathbb{R}\}$  has VC-index,  $V(\mathcal{G}) = 3 < \infty$ . By Theorem 3.6 (and subsequently Theorem 3.4), this is a Donsker class. That is uniformly over  $a, b \in \mathbb{R}$ :

$$\frac{1}{\sqrt{n}} \sum_{i=1}^n \{\mathbb{1}[a < X_i \leq b] - P(a < X_i \leq b)\} \rightsquigarrow \mathbb{G}.$$

for some tight element  $\mathbb{G}$  on  $\ell^\infty(\mathcal{G})$ .

All together, this is interesting for showing that collections of indicator functions are Donsker, but what about arbitrary classes of functions?

### 3.6.2 VC Classes of Functions

**Definition 3.21** (Subgraph). The subgraph of a function  $f : \mathcal{X} \rightarrow \mathbb{R}$  is the subset of  $\mathcal{X} \times \mathbb{R}$  given by

$$\{(x, t) : t < f(x)\}.$$

**Remark.** Note that the subgraph does not include the points  $\{(x, y) : y = f(x)\}$

Figure 3.1: The subgraph of  $f : \mathbb{R}^+ \rightarrow \mathbb{R}^+$ ,  $x \mapsto \sqrt{x}$  is shaded in gray.

**Definition 3.22** (VC Class for Functions). A collection of functions  $\mathcal{F}$  is called a VC-subgraph class, or just a VC-class if the collections of all subgraphs of the functions in  $\mathcal{F}$  forms a VC-class of sets in  $\mathcal{X} \times \mathbb{R}$ . Let  $V(\mathcal{F})$  be the VC-index of the set of subgraphs of functions in  $\mathcal{F}$ .

Just as for sets, the covering numbers of VC-classes of functions grow at a polynomial rate.

**Theorem 3.7** (Theorem 2.6.7 VdV&W). Let  $\mathcal{F}$  be a VC-class of functions with measurable envelope  $F$ . Then for  $r \geq 1$  and any probability measure  $Q$  with  $\|F\|_{Q,r} > 0$ ,

$$\mathcal{N}(\epsilon \|F\|_{Q,r}, \mathcal{F}, L_r(Q)) \leq KV(\mathcal{F}) (16e)^{V(\mathcal{F})} \left(\frac{1}{\epsilon}\right)^{r(V(\mathcal{F})-1)} \quad (3.16)$$

for a universal constant  $K$  and  $0 < \epsilon < 1$ .

*Proof.* Let  $\mathcal{C}$  be the set of all subgraphs  $C_f$  of functions  $f \in \mathcal{F}$ . That is

$$\begin{aligned} C_f &= \{(x, t) : t < f(x)\} \\ \mathcal{C} &= \{C_f : f \in \mathcal{F}\} \end{aligned}$$

By Fubini's Theorem,  $Q|f-g| = (Q \times \lambda)(C_f \triangle C_g)$  where  $A \triangle B = (A \setminus B) \cup (B \setminus A) = (A \cup B) \setminus (A \cap B)$  is the symmetric difference of two sets.<sup>6</sup> Renormalize  $Q \times \lambda$  to a probability measure on the set  $\{(x, t) : |t| \leq F(x)\}$

Figure 3.2: The symmetric difference  $C_f \triangle C_g$  is shaded in yellow

by defining  $P = \frac{(Q \times \lambda)}{2QF}$ . Then, by the result in Theorem 3.6 we have that

$$\mathcal{N}(\epsilon(2QF), \mathcal{F}, L_1(Q)) = \mathcal{N}(\epsilon, \mathcal{C}, L_1(P)) \leq KV(\mathcal{F}) \left( \frac{4e}{\epsilon} \right)^{V(\mathcal{F})-1}.$$

By adjusting the constant  $K$  to convert  $(4e)^{V(\mathcal{F})-1}$  to a  $(16e)^{V(\mathcal{F})}$  this concludes the proof for  $r = 1$ .

For  $r > 1$  note that  $2F$  is an envelope for  $\mathcal{F}_\infty$ , a property that we have used before. Define  $R$  to be the probability measure with density  $F^{r-1}/QF^{r-1}$  with respect to  $Q$ . That is  $R\bar{f} = Q\left(\bar{f} \frac{F^{r-1}}{QF^{r-1}}\right)$  for any function  $\bar{f} : \mathcal{X} \rightarrow \mathbb{R}$ . Then:

$$Q|f-g|^r \leq Q|f-g|(2F)^{r-1} = 2^{r-1}R|f-g|QF^{r-1}.$$

Thus the  $L_r(Q)$  distance is bounded by the distance  $2(QF^{r-1})^{1/r}\|f-g\|_{R,1}^{1/r}$ . This gives that

$$\mathcal{N}(\epsilon 2\|F\|_{Q,r}, \mathcal{F}, L_r(Q)) \leq \mathcal{N}(\epsilon^r\|F\|_{R,1}, \mathcal{F}, L_1(R)).$$

which can be uniformly bounded by the result for  $r = 1$ . This gives the result after noting that  $\frac{1}{\epsilon^r} = \left(\frac{1}{\epsilon}\right)^r$ .  $\square$

If the conditions of Theorem 3.7 are satisfied with  $V(\mathcal{F}) < \infty$  then we can bound the (UEB) with

$$\begin{aligned} \int_0^\infty \sup_{Q \in \mathcal{Q}} \sqrt{\log \mathcal{N}(\epsilon\|F\|_{Q,2}, \mathcal{F}, L_2(Q))} d\epsilon &\lesssim \int_0^1 \sqrt{\log \mathcal{N}(\epsilon\|F\|_{Q,2}, \mathcal{F}, L_1(Q))} d\epsilon \\ &\lesssim \int_0^1 \sqrt{\log \tilde{K} \left(\frac{1}{\epsilon}\right)^{2(V(\mathcal{F})-1)}} d\epsilon < \infty \end{aligned}$$

where the first step is using the fact that if  $\epsilon > 1$  we only need one ball of radius  $\epsilon\|F\|_{Q,2}$  to cover  $\mathcal{F}$  under  $Q$  and then noting that the covering numbers under  $L_1$  differ from the covering numbers under  $L_2$  by a bounded constant.

<sup>6</sup>It is useful to recall that

$$\begin{aligned} C_f \cup C_g &= \{(x, t) : t < f(x) \text{ or } t < g(x)\} \\ C_f \cap C_g &= \{(x, t) : t < f(x) \text{ and } t < g(x)\} \end{aligned}$$

and also that  $Q$  is a probability measure over  $\mathcal{X}$  whereas  $\lambda$  is a measure over  $\mathbb{R}$ . Both  $C_f$  and  $C_g$  are subsets of  $\mathcal{X} \times \mathbb{R}$ .

**Example.** Suppose  $\mathcal{F} = \left\{ \sum_{j=1}^K \beta_j \phi_j(x), (\beta_1, \dots, \beta_K) \in \mathbb{R}^K \right\}$ . Then  $V(\mathcal{F}) \leq K + 2$ . How? Recall that we are considering the VC-index of the collection

$$\mathcal{C} = \left\{ \{(x, t) : t \leq \beta' \phi(x)\} : \beta \in \mathbb{R}^K \right\} \subseteq 2^{\mathcal{X} \times \mathbb{R}}.$$

Pick  $(x_1, t_1), \dots, (x_{K+2}, t_{K+2})$  distinct points in  $\mathcal{X} \times \mathbb{R}$ . Then for any  $f \in \mathcal{F}$ :

$$\begin{bmatrix} f(x_1) \\ \vdots \\ f(x_{K+2}) \end{bmatrix} = \beta_1 \begin{bmatrix} \phi_1(x_1) \\ \vdots \\ \phi_1(x_{K+2}) \end{bmatrix} + \dots + \beta_K \begin{bmatrix} \phi_K(x_1) \\ \vdots \\ \phi_K(x_{K+2}) \end{bmatrix}.$$

so  $(f(x_1), \dots, f(x_{K+2}))$  is in a subspace of  $\mathbb{R}^{K+2}$  of dimension  $K$  for any  $f \in \mathcal{F}$ . Similarly, we can show that  $f(x) - t$  is in a subspace of dimension  $K + 1$  for any fixed  $f \in \mathcal{F}$  and  $t_1, \dots, t_{K+2}$ .

To show that  $V(\mathcal{F}) \leq K + 2$  we want to show that  $\{(x_1, t_1), \dots, (x_{K+2}, t_{K+2})\}$  cannot be shattered by subgraphs of  $\mathcal{F}$ . That is we want a subset  $A \subseteq \{(x_1, t_1), \dots, (x_{K+2}, t_{K+2})\}$  such that  $\nexists f \in \mathcal{F}$  with

$$A = \{(x_1, t_1), \dots, (x_{K+2}, t_{K+2})\} \cap \{(x, t) : t < f(x)\}.$$

Since for any fixed  $f \in \mathcal{F}$ ,  $t_1, \dots, t_{K+2}$ ,  $f(x_1) - t_1, \dots, f(x_{K+2}) - t_{K+2}$  is in a subspace of dimension  $K + 1$  of  $\mathbb{R}^{K+2}$  for any  $x_1, \dots, x_{K+2}$ , there exists a vector  $a \neq 0$  orthogonal to this subspace such that

$$\sum_{j=1}^{K+2} a_j (f(x_j) - t_j) = 0 \implies \sum_{a_j > 0} a_j (f(x_j) - t_j) = \sum_{a_j \leq 0} (-a_j) (f(x_j) - t_j).$$

Pick the indices corresponding to the positive  $a_j > 0$  values (the indices on the LHS after the implication) and consider  $A = \{(x_j, t_j) : a_j > 0\}$ . Since  $a \neq 0$  we know this set is non-empty. If  $A = \{(x_1, t_1), \dots, (x_{K+2}, t_{K+2})\} \cap \{(x, t) : t < f(x)\}$  for some  $f \in \mathcal{F}$  then

$$\sum_{a_j > 0} a_j (f(x_j) - t_j) > 0 \geq \sum_{a_j \leq 0} (-a_j) (f(x_j) - t_j).$$

which is a contradiction as these two are equal as demonstrated above. Thus  $V(\mathcal{F}) \leq K + 2$ . However, notice that unless the functions  $\phi_j(x)$  are all uniformly equal to 0, the class  $\mathcal{F}$  does not have an envelope with  $P^*F < \infty$ , so it is neither Glivenko-Cantelli nor Donsker unless we restrict the parameter space (the range of  $\beta_1, \dots, \beta_K$ ). It is useful to consider the following sanity check:

$$\sup_{\beta_1, \dots, \beta_K} \left| \frac{1}{n} \sum_{i=1}^n (\beta_1 \phi_1(x_i) + \dots + \beta_K \phi_K(x_i)) - \mathbb{E}[\dots] \right| = \infty.$$

This example can be generalized and outlines the proof for the next lemma

**Lemma 3.11** (VC Dimension of Finite Dimensional Vector Spaces). *Any finite dimensional vector space  $\mathcal{F}$  of measurable functions  $f : \mathcal{X} \rightarrow \mathbb{R}$  is a VC function class with  $V(\mathcal{F}) \leq \dim(\mathcal{F}) + 2$ .*

*Proof.* Follows the example above. Can also be found as Lemma 2.6.16 in VanDerVaart and Wellner.  $\square$

Another examples of a VC function class is given below:

**Lemma 3.12** (VC Dimension of Translates). *Let  $\psi : \mathbb{R} \rightarrow \mathbb{R}$  be a monotonic function and let  $\mathcal{F}$  be the set of all translates of  $\psi$ ,  $\mathcal{F} = \{\psi(x - h) : h \in \mathbb{R}\}$ . Then  $V(\mathcal{F}) = 2$ .*

*Proof.* This follows similarly from the example above where we considered the VC-dimension of  $\mathcal{C} = \{(-\infty, b) : a < b\}$ . Without loss of generality suppose that  $\psi$  is decreasing and denote  $\psi_h = \psi(x - h)$ . The subgraphs of  $\psi_h$  are nested in that if  $h > h'$ ,  $C_{h'} \subseteq C_h$  since if  $t < \psi_{h'}(x)$  then  $t < \psi_h(x)$ . Take any two element subset of  $\mathbb{R} \times \mathbb{R}$ :  $\{(x_1, t_1), (x_2, t_2)\}$ . By considering the single element subsets of this set we see that we cannot shatter this set without breaking the nesting of the subgraphs so  $V(\mathcal{F}) = 2$ .  $\square$
